Preface	9
Introduction	10
PART ONE. STATICS OF RIGID BODIES	
Chapter 1. Basic Concepts and Principles	
1. The Subject of Statics	13
2. Force	14
3. Fundamental Principles	16
4. Constraints and Their Reactions	19
5. Axiom of Constraints	22
Chapter 2. Concurrent Force Systems	
6. Geometrical Method of Composition of Concurrent Forces	23
7. Resolution of Forces	25
8. Projection of a Force on an Axis and on a Plane	28
9. Analytical Method of Defining a Force	30
10. Analytical Method for the Composition of Forces	31
11. Equilibrium of a System of Concurrent Forces	32
12. Problems Statically Determinate and Statically Indeterminate	34
13. Solution of Problems of Statics	35
14. Moment of a Force About an Axis (or a Point)	43
15. Varignon's Theorem of the Moment of a Resultant	45
16. Equations of Moments of Concurrent Forces	46
Chapter 3. Parallel Forces and Couples in a Plane	
17. Composition and Resolution of Parallel Forces	47
18. Force Couples. Moment of a Couple	50
19. Equivalent Couples	51
20. Composition of Coplanar Couples. Conditions for the Equilibrium of Couples	53
Chapter 4. General Case of Forces in a Plane	
21. Theorem of the Translation of a Force to a Parallel Position	55
22. Reduction of a Coplanar Force System to a Given Centre	56
23. Reduction of a Coplanar Force System to the Simplest Possible Form	58
24. Conditions for the Equilibrium of a Coplanar Force System.	61
25. Equilibrium of a Coplanar System of Parallel Forces	63
26. Solution of Problems	63
27. Equilibrium of Systems of Bodies	70
28. Distributed Forces	74

Chapter 5. Elements of Graphical Statics

29. Force and String Polygons. Reduction of a Coplanar Force System to Two Forces	78
30. Graphical Determination of a Resultant	80
31. Graphical Determination of a Resultant Couple	80
32. Graphical Conditions of Equilibrium of a Coplanar Force System	81
33. Determination of the Reactions of Constraints	81
34. Graphical Analysis of Plane Trusses	82
35. The Maxwell Diagram	85

Chapter 6. Friction

36. Laws of Static Friction	86
37. Reactions of Rough Constraints. Angle of Friction	88
38. Equilibrium with Friction	89
39. Belt Friction	92
40. Rolling Friction and Pivot Friction	94

Chapter 7. Couples and Forces in Space

41. Moment of a Force About a Point as a Vector	95
42. Moment of a Force with Respect to an Axis	97
43. Relation Between the Moments of a Force about a Point and an Axis	100
44. Vector Expression of the Moment of a Couple	101
45. Composition of Couples in Space. Conditions of Equilibrium of Couples	101
46. Reduction of a Force System in Space to a Given Centre	104
47. Reduction of a Force System in Space to the Simplest Possible Form	106
48. Condition of Equilibrium of an Arbitrary Force System in Space. The Case of Parallel Forces	108
49. Varignon's Theorem of the Moment of a Resultant with Respect to an Axis	109
50. Problems on the Equilibrium of Bodies Subjected to the Action of Force Systems in Space	110
51. Conditions of Equilibrium of a Constrained Rigid Body. Concept of Stability of Equilibrium	117

Chapter 8. Centre of Gravity

52. Centre of Parallel Forces	118
53. Centre of Gravity of a Rigid Body	120
54. Coordinates of Centres of Gravity of Homogeneous Bodies	122
55. Methods of Determining the Coordinates of the Centre of Gravity of Bodies	122
56. Centre of Gravity of Some Homogeneous Bodies	125

PART II. KINEMATICS OF A PARTICLE AND A RIGID BODY**Chapter 9. Rectilinear Motion of a Particle**

57. Introduction to Kinematics	128
58. Equation of Rectilinear Motion	129
59. Velocity and Acceleration of a Particle in Rectilinear Motion	130
60. Some Examples of Rectilinear Motion of a Particle	132
61. Graphs of Displacement, Velocity and Acceleration of a Particle	134
62. Solution of Problems	135

Chapter 10. Curvilinear Motion of a Particle

63. Vector Method of Describing Motion of a Particle	137
64. Velocity Vector of a Particle	138
65. Acceleration Vector of a Particle	139
66. Theorem of the Projection of the Derivative of a Vector	141
67. Coordinate Method of Describing Motion. Determination of the Path, Velocity and Acceleration of a Particle	142
68. Natural Method of Describing Motion. Determination of the Velocity of a Particle	147
69. Tangential and Normal Acceleration of a Particle	148
70. Some Special Cases of Particle Motion	151
71. Velocity in Polar Coordinates	156
72. Graphical Analysis of Particle Motion	156

Chapter 11. Translatory and Rotational Motion of a Rigid Body

73. Motion of Translation	160
74. Rotational Motion of a Rigid Body. Angular Velocity and Angular Acceleration	162
75. Uniform and Uniformly Variable Rotation	164
76. Velocities and Accelerations of the Points of a Rotating Body	166

Chapter 12. Plane Motion of a Rigid Body

77. Equations of Plane Motion. Resolution of Motion into Translation and Rotation	170
78. Determination of the Paths of the Points of a Body	172
79. Determination of the Velocity of Any Point of a Body	173
80. Theorem of the Projections of the Velocities of Two Points of a Body	174
81. Determination of the Velocity of Any Point of a Body Using the Instantaneous Centre of Zero Velocity	175
82. Solution of Problems	178
83. Velocity Diagram	182
84. Determination of the Acceleration of Any Point of a Body	184
85. Instantaneous Centre of Zero Acceleration	191

Chapter 13. Motion of a Rigid Body Having One Fixed Point and Motion of a Free Rigid Body

86. Motion of a Rigid Body Having One Fixed Point	193
87. Velocity and Acceleration of Any Point of a Body	195
88. The Most General Motion of a Free Rigid Body	196

Chapter 14. Resultant Motion of a Particle

89. Relative, Transport, and Absolute Motion	198
90. Composition of Velocities	200
91. Composition of Accelerations. Coriolis Theorem	203
92. Calculation of Coriolis Acceleration	207
93. Solution of Problems	209

Chapter 15. Resultant Motion of a Rigid Body

94. Composition of Translatory Motions	215
95. Composition of Rotations About Two Parallel Axes	215
96. Toothed Spur Gearing	218
97. Composition of Rotations About Two Intersecting Axes	221
98. Composition of a Translation and a Rotation. Screw Motion	223

PART THREE. PARTICLE DYNAMICS

Chapter 16. Introduction to Dynamics. Laws of Dynamics

99. Basic Concepts and Definitions	226
100. The Laws of Dynamics	227
101. Systems of Units	230
102. The Problems of Dynamics for a Free and a Constrained Particle	230
103. Solution of the First Problem of Dynamics	231

Chapter 17. Differential Equations of Motion for a Particle and Their Integration

104. Rectilinear Motion of a Particle	233
105. Solution of Problems	236
106. Body Falling in a Resisting Medium (in Air)	241
107. Curvilinear Motion of a Particle	244
108. Motion of a Particle Thrown at an Angle to the Horizon in a Uniform Gravitational Field	245

Chapter 18. General Theorems of Particle Dynamics

109. Momentum and Kinetic Energy of a Particle	248
110. Impulse of a Force	249
111. Theorem of the Change in the Momentum of a Particle	250
112. Work Done by a Force. Power	251
113. Examples of Calculation of Work	254
114. Theorem of the Change in the Kinetic Energy of a Particle.	256
115. Solution of Problems	258
116. Theorem of the Change in the Angular Momentum of a Particle (the Principle of Moments)	264

Chapter 19. Constrained Motion of a Particle and D'Alembert's Principle

117. Equations of Motion of a Particle Along a Given Fixed Curve	268
118. Determination of the Reactions of Constraints	270
119. D'Alembert's Principle	272

Chapter 20. Relative Motion of a Particle

120. Equations of Relative Motion and Rest of a Particle	275
121. Effect of the Rotation of the Earth on the Equilibrium and Motion of Bodies	278
122. Deflection of a Falling Particle from the Vertical by the Earth's Rotation	281

Chapter 21. Vibration of a Particle

123. Free Harmonic Motion	284
124. The Simple Pendulum	288
125. Damped Vibrations	289
126. Forced Vibrations. Resonance	291

Chapter 22. Motion of a Body in the Earth's Gravitational Field

127. Motion of a Particle Thrown at an Angle to the Horizon in the Earth's Gravitational Field	299
128. Artificial Earth Satellites. Elliptical Paths	304

PART IV. DYNAMICS OF A SYSTEM AND A RIGID BODY

Chapter 23. Introduction to the Dynamics of a System. Moments of Inertia of Rigid Bodies	
129. Mechanical Systems. External and Internal Forces	308
130. Mass of a System. Centre of Mass	309
131. Moment of Inertia of a Body About an Axis. Radius of Gyration	310
132. Moments of Inertia of Some Homogeneous Bodies	311
133. Moments of Inertia of a Body About Parallel Axes. The Parallel-Axis (Huygens') Theorem	313
Chapter 24. Theorem of the Motion of the Centre of Mass of a System	
131. The Differential Equations of Motion of a System	315
135. Theorem of the Motion of Centre of Mass	316
136. The Law of Conservation of Motion of Centre of Mass	317
137. Solution of Problems	319
Chapter 25. Theorem of the Change in the Linear Momentum of a System	
138. Linear Momentum of a System	323
139. Theorem of the Change in Linear Momentum	324
140. The Law of Conservation of Linear Momentum	325
141. Solution of Problems	326
142. Bodies Having Variable Mass. Motion of a Rocket	329
Chapter 26. Theorem of the Change in the Angular Momentum of a System	
143. Total Angular Momentum of a System	332
144. Theorem of the Change in the Angular Momentum of a System (the Principle of Moments)	333
145. The Law of Conservation of the Total Angular Momentum	334
146. Solution of Problems	337
Chapter 27. Theorem of the Change in the Kinetic Energy of a System	
147. Kinetic Energy of a System	339
148. Theorem of the Change in the Kinetic Energy of a System	344
149. Some Cases of Computation of Work	346
150. Solution of Problems	348
151. Field of Force. Potential Energy	353
152. The Law of Conservation of Mechanical Energy	355
Chapter 28. Some Cases of Rigid-Body Motion	
153. Rotation of a Rigid Body	356
154. The Compound Pendulum	359
155. Determination of Moments of Inertia by Experiment	361
156. Plane Motion of a Rigid Body	361
157. Approximate Theory of Gyroscopic Action	368
Chapter 29. D'Alembert's Principle. Forces Acting on the Axis of a Rotating Body	
158. D'Alembert's Principle for a System	373
159. The Principal Vector and the Principal Moment of the Inertia Forces of a Rigid Body	374
160. Solution of Problems	376

161. Dynamical Pressures on the Axis of a Rotating Body	380
162. The Principal Axes of Inertia of a Body. Dynamic Balancing of Masses	382
Chapter 30. The Principle of Virtual Work and the General Equation of Dynamics	
163. Virtual Displacements of a System. Degrees of Freedom	386
164. Ideal Constraints	388
165. The Principle of Virtual Work	388
166. Solution of Problems	390
167. The General Equation of Dynamics	395
Chapter 31. The Theory of Impact	
168. The Fundamental Equation of the Theory of Impact	398
169. General Theorems of the Theory of Impact	400
170. Coefficient of Restitution	401
171. Impact of a Body Against a Fixed Obstacle	403
172. Direct Central Impact of Two Bodies (Impact of Spheres)	405
173. Loss of Kinetic Energy in Perfectly Inelastic Impact. Carnot's Theorem	407
174. Impact with a Rotating Body	409
Name Index	414
Subject Index	414

PREFACE

This book is designed for students of higher and secondary technical schools. It treats of the basic methods of theoretical mechanics and their spheres of application. It also briefly examines motion in a gravitational field (artificial satellites and elliptical trajectories), the motion of bodies with variable mass (e.g., rockets), the elementary theory of gyroscopic motion, and other topics. These questions are of such importance today that no course of mechanics, even a short one, can neglect them altogether.

The organisation of this book is based on the profound conviction, borne out by many years of experience, that the best way of presenting study material, especially when it is contained in a short course, is to proceed from the particular to the general. Accordingly, in this book, plane statics comes before three-dimensional statics, particle dynamics before systems dynamics, rectilinear motion before curvilinear motion, etc. Such an arrangement helps the student to understand and digest the material better and faster, and the teaching process itself is made more graphic and consistent.

Alongside of the geometrical and analytical methods of mechanics the book makes wide use of the vector method as one of the main generally accepted methods which, furthermore, possesses a number of indisputable advantages. As a rule, however, only those vector operations are used which are similar to corresponding operations with scalar quantities and which do not require additional acquaintance with many new concepts.

Considerable space—more than one-third of the total volume of the book—is given to examples and worked problems. They were chosen with an eye to ensure a clear comprehension of the relevant mechanical phenomena, and they embrace all the main types of problems and methods of problem solution. The problem solutions contain instructions designed to assist the student in his independent work on the course. In this respect, the book should prove useful to students from many fields interested in advancing their knowledge of the subject.

INTRODUCTION

The progress of technology confronts the engineer with a wide variety of problems connected with structural design (buildings, bridges, canals, dams, etc.), the design, manufacture and operation of various machines, motors and means of locomotion, such as automobiles, steam engines, ships, aircraft and rockets. Despite the diversity of problems that arise, their solution, at least in part, is based on certain general physical principles common to all of them, namely, the laws governing the motion and equilibrium of material bodies.

The science which treats of the general laws of motion and equilibrium of material bodies and of their resulting mutual interactions is called *theoretical mechanics*. This science constitutes one of the scientific bedrocks of modern engineering*.

By *motion* in mechanics we mean any change in the relative positions of material bodies in space which occurs in the course of time. By *mechanical interaction* between bodies is meant such reciprocal action which changes or tends to change the state of motion or the shape of the bodies involved (deformation). The physical measure of such mechanical interaction is called *force*.

Theoretical mechanics is primarily concerned with the general laws of motion and equilibrium of material bodies under the action of forces to which they are subjected.

According to the nature of the problems treated, mechanics is divided into *statics*, *kinematics*, and *dynamics*. Statics studies the laws of composition of forces and the conditions of equilibrium of material bodies subjected to the action of forces. Kinematics deals with the general geometrical properties of the motion of bodies. Finally, dynamics studies the laws of motion of material bodies under the action of forces.

* Mechanics, in the broad sense of the term, may be defined as the science which deals with the solution of all problems connected with the motion or equilibrium of material bodies and the resulting interactions between them. Theoretical mechanics, as a part of general mechanics, treats only of the *general laws* of motion and interaction of material bodies, i.e., laws which apply equally, for example, to the Earth's motion around the Sun, or to the flight of a rocket. Other branches of mechanics cover a variety of general and specialised engineering disciplines treating of the design and calculation of specific structures, motors and other machines and mechanisms or their parts. All these disciplines are based on the laws and methods of theoretical mechanics.

According to the nature of the objects under study, theoretical mechanics is subdivided into: a) mechanics of a particle, i.e., of a body whose dimensions can be neglected in studying its motion or equilibrium, and systems of particles; b) mechanics of a rigid body, i.e., a body whose deformation can be neglected in studying its motion or equilibrium; c) mechanics of bodies of variable mass (i.e., bodies whose mass changes with time); d) mechanics of deformable bodies (the theories of plasticity and elasticity); e) mechanics of liquids (fluid mechanics); f) mechanics of gases (aerodynamics).

The general course of theoretical mechanics conventionally treats of the mechanics of particles and rigid bodies and the general laws of motion of systems of particles.

The emergence and development of mechanics* as a science are inseparable from the development of the productive forces of society and the level of industry and technology at each stage of this development.

The study of the so-called simple machines (the pulley, the winch, the lever, and the inclined plane) and the general study of equilibrium of bodies (statics) began in ancient times when the requirements of engineering were limited mainly to the needs of building construction. The fundamentals of statics are already found in the works of Archimedes (287-212 B.C.), one of the great scholars of antiquity.

Compared with statics, dynamics developed at a much later stage. The credit of laying the foundations of dynamics goes to Galileo Galilei (1564-1642) and Sir Isaac Newton (1643-1727). The fundamental laws of so-called classical mechanics, now known as Newton's laws, were formulated by Newton in his "Mathematical Principles of Natural Philosophy" published in 1687. Newton's laws have since been confirmed by a tremendous amount of practical evidence in the course of the technological advance of human society. This permits us to regard as conclusive our concepts of mechanics based on Newton's laws; and the engineer can, therefore, confidently rely on them in his practical work**.

* The term "mechanics" first appears in the works of Aristotle (384-322 B.C.), the great philosopher of antiquity. It is derived from the greek word μηχανή, which has the meaning of "structure", "machine", "device".

** Subsequent scientific developments have revealed that at velocities approaching that of light the motion of bodies is governed by the mechanical laws of the theory of relativity, while the motion of "elementary" particles (electrons, positrons, etc.) is described by the laws of quantum mechanics. These discoveries, however, only served to define more accurately the spheres of application of classical mechanics and reaffirm the validity of its laws for the motion of all bodies other than "elementary" particles at all velocities not approaching the velocity of light, i.e., for motions with which engineering and celestial mechanics are primarily concerned.

In the 18th century, analytical methods, i.e., methods based on the application of differential and integral calculus, began to develop rapidly in mechanics. The methods of solving problems of particle and rigid body dynamics by the integration of differential equations were elaborated by the great mathematician and mechanic Leonhard Euler (1707-1783). Among the other major contributions to the progress of mechanics were the works of the outstanding French scientists Jean d'Alembert (1717-1783), who enunciated his famous principle for solving problems of dynamics, and Joseph Lagrange (1736-1813), who evolved the general analytical method of solving problems of dynamics on the basis of d'Alembert's principle and the principle of virtual work. Today analytical methods predominate in solving problems of dynamics.

Kinematics emerged as a special branch of mechanics only in the first half of the 19th century under pressure from the growing machine-building industry. Today kinematics is essential in studying the motion of machines and mechanisms.

In Russia, the study of mechanics was greatly influenced by the works of the great Russian scientist and thinker Mikhail Lomonosov (1711-1765) and of Leonhard Euler, who for many years lived and worked in St. Petersburg. Prominent among the galaxy of Russian scientists who contributed to the development of different divisions of theoretical mechanics were M. V. Ostrogradsky (1801-1861), the author of a number of important studies in analytical methods of problem solution in mechanics; P. L. Chebyshev (1821-1894), who started a new school in the study of the motion of mechanisms; S. V. Kovalenskaya (1850-1891), who solved one of the most difficult problems of rigid body dynamics; A. M. Lyapunov (1857-1918), who elaborated new methods of studying the stability of motion; I. V. Meshchersky (1859-1935), who laid the foundations of the mechanics of bodies of variable mass; K. E. Tsiolkovsky (1857-1935), who made a number of fundamental discoveries in the theory of jet propulsion; and A. N. Krylov (1863-1945), who elaborated the theory of vessels and contributed much to the development of the theory of gyroscopic instruments.

Of tremendous importance to the further study of mechanics were the works of N. E. Zhukovsky (1847-1921), the "Father of Russian aviation", and his best pupil S. A. Chaplygin (1869-1942). Zhukovsky's special contribution was in the field of applying methods of mechanics to the solution of actual engineering problems. Zhukovsky's ideas have greatly influenced the teaching of theoretical mechanics in Soviet higher technical educational establishments.

PART ONE

STATICS OF RIGID BODIES

Chapter 1

BASIC CONCEPTS AND PRINCIPLES

1. The Subject of Statics. *Statics* is the branch of mechanics which studies the laws of composition of forces and the conditions of equilibrium of material bodies under the action of forces.

Equilibrium is the state of rest of a body relative to other material bodies. If the frame of reference relative to which a body is in equilibrium can be treated as fixed, the given body is said to be in absolute equilibrium; otherwise it is in relative equilibrium. In statics we shall study only absolute equilibrium. In actual engineering problems equilibrium relative to the earth or to bodies rigidly connected with the earth is treated as absolute equilibrium. The justification of this premise will be found in the course of dynamics, where the concept of absolute equilibrium will be defined more strictly. And there, too, we shall examine the concept of relative equilibrium.

Conditions of equilibrium depend on whether a given body is solid, liquid or gaseous. The equilibrium of liquids and gases is studied in the courses of hydrostatics and aerostatics respectively. General mechanics deals essentially with the equilibrium of solids.

All solid bodies change their shape to a certain extent when subjected to external forces. This is known as deformation. The amount of deformation depends on the material, shape and dimensions of the body and the acting forces. In order to ensure the necessary strength of engineering structures and elements, the material and dimensions of various parts are chosen in such a way that the deformation under specified loads would remain tolerably small*. This makes it possible, in studying the general conditions of equilibrium, to treat solid bodies as undeformable or absolutely rigid, ignoring the small deformations that actually occur. An *absolutely rigid body* is said to be one in which the

* For example, the material and the diameter of rods in various structures are so chosen that, under the working loads, they would extend (or contract) by no more than one-thousandth of their original length. Deformations of a similar order are tolerated in bending, torsion, etc.

distance between any pair of particles is always constant. In solving problems of statics, in this book we shall always consider bodies as absolutely rigid, and will simply refer to them as rigid bodies. It will be shown at the end of § 3 that the laws of equilibrium of absolutely rigid bodies can be applied not only to solid bodies with relatively small deformation, but to any deformable bodies as well. Thus the sphere of application of rigid body statics is extremely wide.

Deformation is of great importance in calculating the strength of engineering structures and machine parts. These questions are studied in the courses of strength of materials and theory of elasticity.

For a rigid body to be in equilibrium (at rest) when subjected to the action of a system of forces, the system must satisfy certain *conditions of equilibrium*. The determination of these conditions is one of the principal problems of statics. In order to find out the equilibrium conditions for various force systems and to solve other problems of mechanics one must know the principles of the composition, or addition, of forces acting on a rigid body, the principles of replacing one force system by another and, particularly, the principles of reducing a given force system to as simple a form as possible. Accordingly, statics of rigid bodies treats of two basic problems: (1) the composition of forces and reduction of force systems acting on rigid bodies to as simple a form as possible, and (2) determination of the conditions for the equilibrium of force systems acting on rigid bodies.

The problems of statics may be solved either by geometrical constructions (the graphical method) or by mathematical calculus (the analytical method). The present course discusses both methods, but it should always be borne in mind that geometrical constructions are of special importance in solving problems of mechanics.

2. Force. The state of equilibrium or motion of a given body depends on its mechanical interactions with other bodies, i.e., on the loads, attractions or repulsions it experiences as a result of such interactions. *In mechanics, the quantitative measure of the mechanical interaction of material bodies is called force.*

Quantities employed in mechanics are either scalar, i.e., possessing magnitude alone, or vector, i.e., quantities which besides magnitude are also characterised by direction in space.

Force is a vector quantity. Its action on a body is characterised by (1) its *magnitude*, (2) its *direction*, and (3) its *point of application*.

The magnitude of a force is expressed in terms of a standard force accepted as a unit. In statics, the unit of force is the

kilogram (1 kg^*). Static forces are measured with dynamometers, which are described in the course of physics. The direction and the point of application of a force depend on the nature of the interaction between the given bodies and their respective positions. The force of gravity acting on a body, for example, is always directed vertically downwards; the forces with which two smooth contacting spheres act on each other are normal to both their surfaces at the points of contact and are applied at those points, etc.

Force is represented graphically by a directed straight line segment with an arrowhead. The length of the line (AB in Fig. 1) denotes the magnitude of the force to some scale, the direction of the line shows the direction of the force, its initial point (point A in Fig. 1) usually indicating the point of application of the force, though sometimes it may be more convenient to depict a force as "pushing" a body with its tip (as in Fig. 4c). The line DE along which the force is directed is called the *line of action* of the force. We shall denote force, as all vector quantities, by a boldface-type letter (\mathbf{F}) or by overlined standard-type letters (\overline{AB}). The absolute value of a force is represented by the symbol $|\mathbf{F}|$ (two vertical lines "flanking" a vector) or simply by a standard-type letter (F). (In handwriting overlined letters are used.)

Fig. 1.

We shall call any set of forces acting on a rigid body a *force system*. We shall also use the following definitions:

1. A body not connected with other bodies and which from any given position can be displaced in any direction in space is called a *free body*.

2. If a free rigid body subject to a force system is at rest, the system is said to be *balanced*.

3. If a force system acting on a free rigid body can be replaced by another force system without disturbing the body's initial condition of rest or motion, the two systems are said to be *equivalent*.

4. If a given force system is equivalent to a single force, that force is the *resultant* of the system. Thus, a *resultant* is a single force capable of replacing the action of a system of forces on a rigid body.

A force equal in magnitude, collinear with, and opposite in direction to the resultant is called an *equilibrant* force.

* Physicists often distinguish between the force unit and the mass unit by denoting the kilogram force by the symbol kG and the kilogram mass by kg . In this book "kilogram" shall always refer to force.

5. Forces acting on a rigid body can be divided into two groups: external and internal forces. *External* forces represent the action of other material bodies on the particles of a given body. *Internal* forces are those with which the particles of a given body act on each other.

6. A force applied to one point of a body is called a *concentrated* force. Forces acting on all the points of a given volume or given area of a body are called *distributed* forces.

A concentrated force is a purely notional concept, insofar as it is actually impossible to apply a force to a single point of a body. Forces treated in mechanics as concentrated are in fact the resultants of corresponding systems of distributed forces.

Thus, the force of gravity acting on a rigid body, as conventionally treated in mechanics, is the resultant of the gravitational forces acting on its particles. The line of action of this resultant force passes through the body's centre of gravity*.

3. Fundamental Principles. All theorems and equations in statics are deduced from a few fundamental principles, which are accepted without mathematical proof, and are known as the principles, or axioms, of statics. The principles of statics represent general formulations obtained as a result of a vast number of experiments with, and observations of, the equilibrium and motion of bodies and which, furthermore, have been consistently confirmed by actual experience. Some of these principles are corollaries of the fundamental laws of mechanics, which will be examined in the course of dynamics.

Fig. 2.

1st Principle. *A free rigid body subjected to the action of two forces can be in equilibrium if, and only if, the two forces are equal in magnitude ($F_1 = F_2$), collinear, and opposite in direction (Fig. 2).*

The 1st principle defines the simplest balanced force system, since we know from experience that a free body subjected to the action of a single force cannot be in equilibrium.

2nd Principle. *The action of a given force system on a rigid body remains unchanged if another balanced force system is added to, or subtracted from, the original system.*

This principle establishes that two force systems differing from each other by a balanced system are equivalent.

* The determination of the centre of gravity of bodies will be discussed in Chapter 8. Meanwhile it may be noted that if a homogeneous body has a centre of symmetry (e.g., a rectangular beam, a cylinder, a sphere, etc.) its centre of gravity is in the centre of symmetry.

Corollary of the 1st and 2nd Principles. The point of application of a force acting on a rigid body can be transferred to any other point on line of action of the force without altering its effect. This is known as the principle of transmissibility.

Consider a rigid body with a force F applied at a point A (Fig. 3). Now take an arbitrary point B on the line of action of the force and apply to that point two equal and opposite forces F_1 and F_2 such that $F_1 = F$ and $F_2 = -F$. This operation does not affect the action of F on the body. From the 1st principle it follows that forces F and F_2 also form a balanced system and thus cancel each other*, leaving force F_1 equal to F in magnitude and direction, with the point of application shifted to point B .

Fig. 3.

Thus the vector denoting force F can be regarded as applied at any point along the line of action (such a vector is called a *sliding vector*).

This principle holds good only for forces acting on absolutely rigid bodies. In engineering problems it can be used only when we determine the conditions of equilibrium of a structure without taking into account the internal stresses experienced by its parts.

For example, the rod AB in Fig. 4a will be in equilibrium if $F_1 = F_2$. It will remain in equilibrium if both forces are transferred to point C (Fig. 4b) or if force F_1 is transferred to point B and force F_2 to point A (Fig. 4c). The stresses in the rod, however, differ in each case. In the first case the rod is in tension, in the second there is no internal stress, and in the third it is in compression**. Consequently, the principle of transmissibility cannot be employed in determining internal stresses.

Fig. 4.

* We shall denote cancelled or transferred forces in diagrams by a dash across the respective vectors.

** For the rod to be stretched (or compressed) with a force F_1 , the force should be applied at one end of the rod, with the other end supported rigidly or constrained by a force $F_2 = -F_1$, as in Fig. 4. The tension (or thrust) is the same in both cases and is equal to F_1 , and not to $2F_1$ as is sometimes erroneously supposed.

3rd Principle (the Parallelogram Law). *Two forces applied at one point of a body have as their resultant a force applied at the same point and represented by the diagonal of a parallelogram constructed with the two given forces as its sides.*

Vector R , which is the diagonal of the parallelogram with vectors F_1 and F_2 as its sides (Fig. 5), is called the geometrical sum of the vectors F_1 and F_2 :

$$R = F_1 + F_2.$$

Fig. 5.

Hence, the 3rd principle can also be formulated as follows: *The resultant of two forces applied at one point of a body is the geometrical (vector) sum of those forces and is applied at that point.*

It is important to discriminate between the concepts of a sum of forces and their resultant. Consider, say, a body to which two forces F_1 and F_2 are applied at points A and B (Fig. 6). The sum of the two forces can be found by laying them off from any point in the body. In Fig. 6, force Q is the sum of forces F_1 and F_2 ($Q = F_1 + F_2$, as the diagonal of the corresponding parallelogram). But Q is not the resultant of the two forces, for it will be readily observed that Q alone cannot replace the action of F_1 and F_2 on the body. Moreover, forces F_1 and F_2 , as we shall learn later in § 47, have no resultant at all.

Fig. 6.

4th Principle. *To any action of one material body on another there is always an equal and opposite reaction, or, reaction is always equal to action.*

Fig. 7.

The law of action and reaction is one of the fundamental laws of mechanics. It follows from it that when a body A acts on a body B with a force F , body B simultaneously acts on body A with a force F' equal in magnitude, collinear with, and opposite in sense to force F ($F' = -F$) (Fig. 7). Forces F and F' , however, do not form a balanced system as they are applied to different bodies.

Internal Forces. It follows from the 4th principle that any two particles of a rigid body act on each other with forces

equal in magnitude and opposite in sense. Since in studying the general conditions of equilibrium a body can be treated as rigid, all internal forces (according to the 1st principle) form a balanced system and (according to the 2nd principle) can be neglected and only the external forces acting on a given solid body or structure have to be taken into account. Unless otherwise expressly stated, the term "force" will henceforth be used in the sense of "external force".

5th Principle (Principle of Solidification). *If a freely deformable body subjected to the action of a force system is in equilibrium, the state of equilibrium will not be disturbed if the body solidifies (becomes rigid).*

The idea expressed in this principle is self-evident, for, obviously, the equilibrium of a chain will not be disturbed if its links are welded together, and a flexible string will remain in equilibrium if it turns into a bent rigid rod. Since the same force system acts on a reposing body before and after solidification, the 5th principle can also be formulated as follows: *If a freely deformable body is in equilibrium, the forces acting on it satisfy the conditions for the equilibrium of a rigid body; for a deformable body, however, these conditions, though necessary, may not be sufficient.*

For example, for a flexible string with two forces applied at its ends to be in equilibrium, the same conditions are necessary as for a rigid rod (the forces must be of equal magnitude and directed along the string in opposite directions). These conditions, though, are not sufficient. For the string to be in equilibrium the forces must be tensile, i.e., they must stretch the body as shown in Fig. 4a.

The principle of solidification is widely employed in engineering problems. It makes it possible to determine equilibrium conditions by treating a flexible body (a belt, cable, chain, etc.), or a collapsible structure as a rigid body and to apply to it the methods of rigid-body statics. If the equations obtained for the solution of a problem prove insufficient, additional equations must be derived which take into account either the conditions for the equilibrium of separate parts of the given structure or their deformation (problems requiring consideration of deformation are studied in the course of strength of materials).

4. Constraints and Their Reactions. As has been defined above, a body not connected with other bodies and capable of displacement in any direction is called a free body (e.g., a balloon floating in the air). A body whose displacement in space is restricted by other bodies, either connected to or in contact with

it, is called a **constrained body**. We shall call a **constraint** anything that restricts the displacement of a given body in space.

Examples of constrained bodies are a weight lying on a table or a door swinging on its hinges. The constraints in these cases are the surface of the table, which prevents the weight from falling, and the hinges, which prevent the door from sagging from its jamb.

A body acted upon by a force or forces whose displacement is restricted by a constraint acts on that constraint with a force which is customarily called the **load** or **pressure** acting on that constraint. At the same time, according to the 4th principle, the constraint reacts with a force of the same magnitude and opposite sense. *The force with which a constraint acts on a body, thereby restricting its displacement, is called the force of reaction of the constraint (force of constraint), or simply the reaction of the constraint.*

The procedure will be to call all forces which are not the reactions of constraints (e.g., gravitational forces) *applied* or *active forces*. Characteristic of active forces is that their magnitude and direction do not depend on the other forces acting on a given body. The difference between a force of constraint and an active force is that the magnitude of the former always depends on the active forces and is not therefore immediately apparent: if there are no applied forces acting on a body, the forces of constraint vanish. The reactions of constraints are determined by solving corresponding problems of statics. *The reaction of a constraint points away from the direction in which the given constraint prevents a body's displacement.* If a constraint prevents the displacement of a body in several directions, the sense of the reactions is not immediately apparent and has to be found by solving the problem in hand.

The correct determination of the direction of forces of constraint is of great importance in solving problems of statics. Let us therefore consider the direction of the forces of constraint (reactions) of some common types of constraints (more examples are given in § 26).

1. **Smooth Plane (Surface) or Support.** A smooth surface is one whose friction can be neglected in the first approximation. Such a surface prevents the displacement of a body perpendicular (normal) to both contacting surfaces at their point of contact (Fig. 8a)*. Therefore, *the reaction N of a smooth sur-*

* In Figs 8-11, the applied forces acting on the bodies are not shown. In the cases illustrated in Figs 8 and 9, the reactions act in the indicated directions *regardless* of the applied forces and irrespective of whether the bodies are at rest or in motion.

face or support is directed normal to both contacting surfaces at their point of contact and is applied at that point. If one of the contacting surfaces is a point (Fig. 8b) the reaction is directed normal to the other surface.

Fig. 8.

Fig. 9.

2. String. A constraint provided by a flexible inextensible string (Fig. 9) prevents a body M from receding from the point of suspension of the string in the direction AM . The reaction T of the string is thus directed along the string towards the point of suspension.

3. Cylindrical Pin (Bearing). When two bodies are joined by means of a pin passing through holes in them the connection is called a joint or hinge. The axial line of the pin

Fig. 10.

is called the axis of the joint. Body AB in Fig. 10a is hinged to support D and can rotate freely about the axis of the joint (i.e., in the plane of the diagram); at the same time, point A cannot be displaced in any direction perpendicular to the axis. Thus, the reaction R of a pin can have any direction in the plane perpendicular to the axis of the joint (plane Axy in Fig. 10a). In this case neither the magnitude R nor the direction (angle α) of force R are immediately apparent.

4. **Ball-and-Socket and Step Bearing.** This type of constraint prevents displacement in any direction. Examples of such a constraint is a ball-pivot with which a camera is attached to a tripod (Fig. 10b) and a step bearing (Fig. 10c). The reaction R of a ball-and-socket joint or a pivot can have any direction in space. Neither its magnitude R nor its angles with the x , y , and z axes are immediately apparent.

Fig. 11.

5. **Rod.** If a thin rod with two forces applied at its tips is in equilibrium, the forces, according to the 1st principle, must be collinear and directed along the axis of the rod (see Figs 4a and 4c). Consequently, a rod subjected to forces applied at its tips, where the weight of the rod as compared with the magnitude of the forces can be neglected, can be only under tension or under thrust. Hence, if in a structure such a rod AB is used as a constraint (Fig. 11) the reaction N will be directed along its axis*.

5. **Axiom of Constraints.** The equilibrium of constrained bodies is studied in statics on the basis of the following axiom: Any constrained body can be treated as a free body detached from its constraints, provided the latter are represented by their reactions.

Fig. 12.

For example, the beam AB of weight P in Fig. 12a, for which surface OE , support D , and cable KO are constraints, can be regarded as a free body (Fig. 12b) in equilibrium under the action of the given force P and the reactions N_A , N_D , and T of the constraints. The magnitudes of these reactions, which are unknown,

* Strictly speaking, this is possible only if the ends of the rod are fastened with pins. Actually, however, the reaction of a rod may be regarded as directed along its axis even if the ends are welded (e.g., in trusses composed of triangles).

can be determined from the conditions for the equilibrium of the forces acting on the now free body. This is the basic method of solving problems of statics.

The determination of the reactions of constraints is of practical importance because, from the 4th principle, if we know them, we shall know the loads acting on the constraints, i.e., the basic information necessary to calculate the strength of structural elements.

Chapter 2

CONCURRENT FORCE SYSTEMS

6. Geometrical Method of Composition of Concurrent Forces. In studying statics we shall proceed from simple systems to complex systems. Let us commence, then, with systems of concurrent forces. *Forces whose lines of action intersect at one point are called concurrent* (see Fig. 16a). A system of concurrent forces acting on a rigid body can be replaced by an equivalent force system applied at the same point (A in Fig. 16a).

The problem of determining the resultant of concurrent forces is reduced, according to the 3rd principle of statics, to the composition of the given forces.

1) Composition of Two Forces. The resultant R of two concurrent forces F_1 and F_2 is determined either by the parallelogram rule (Fig. 13a) or by constructing a force triangle (Fig. 13b), which is in fact one-half of the corresponding parallelogram. To construct a force triangle lay off a vector denoting one of the forces from an arbitrary point A_1 , and from its tip lay off a vector denoting the second force. The vector R joining the initial point of the first vector with the terminal point of the second vector denotes the resultant force.

Fig. 13.

The magnitude of the resultant is expressed by the formula

$$R^2 = F_1^2 + F_2^2 - 2F_1F_2 \cos (180^\circ - \alpha),$$

where α is the angle between the two forces. Hence,

$$R = \sqrt{F_1^2 + F_2^2 + 2F_1F_2 \cos \alpha}. \quad (1)$$

The angles β and γ which the resultant makes with the component forces can be determined by the law of sines. As $\sin(180^\circ - \alpha) = \sin \alpha$, we have

$$\frac{F_1}{\sin \gamma} = \frac{F_2}{\sin \beta} = \frac{R}{\sin \alpha}. \quad (2)$$

If the point of intersection of the forces F_1 and F_2 is outside the body (Fig. 14a), the resultant can be found by mentally extending the body as shown by the dashed line. Now we can transfer the forces to point O , construct a force parallelogram, and apply the resultant force R at any point C of the body on the line of action of R .

Fig. 14.

If the lines of action of the component forces F_1 and F_2 intersect outside the diagram (Fig. 14b), a point through which their resultant passes can be found by applying at points A and B two balanced forces P_1 and P_2 ($P_1 = -P_2$) directed along AB . According to the 2nd principle, this does not affect the action of forces F_1 and F_2 on the body. By separately compounding F_1 and P_1 and F_2 and P_2 we obtain a force system equivalent to the F_1, F_2 force system and consisting of two forces whose lines of action intersect at C . Consequently, the resultant R also passes through that point. The vector R can now be determined by constructing a force triangle (Fig. 14b).

2) Composition of Three Non-Coplanar Forces. The resultant R of three concurrent non-coplanar forces F_1, F_2, F_3 is represented by the diagonal of a parallelepiped with the given forces for its edges (the *parallelepiped law*). This rule can be verified by successively applying the parallelogram law (Fig. 15).

Fig. 15.

3) Composition of a System of Forces. By consecutively applying the parallelogram law we can draw the following conclusion: *The resultant of any number of concurrent forces is the geometrical sum of those forces and is applied at their point of intersection.* The geometrical sum R of all the forces of a system is called the *principal vector* of that system. The principal vector of a force system can be determined either by successively compounding the forces of the system according to the parallelogram law, or by constructing a force polygon. The latter method is simpler and more convenient. In order to find the resultant of forces $F_1, F_2, F_3, \dots, F_n$ (Fig. 16a) lay off to scale from an arbitrary point O (Fig. 16b) a vector Oa denoting

force F_1 . Now from point a lay off vector \overline{ab} denoting force F_2 , from point b lay off vector \overline{bc} denoting force F_3 , and so on; from the tip m of the penultimate vector lay off vector \overline{mn} denoting force F_n . Vector $\overline{On} = R$, laid off from the initial point of the first vector to the tip of the last vector, represents the geometrical sum, or the principal vector, of the component forces:

$$R = F_1 + F_2 + \dots + F_n \quad \text{or} \quad R = \sum F_k. \quad (3)$$

The magnitude and direction of R do not depend on the order in which the vectors are laid off. It will be noted that the construction carried out is in effect a consecutive application of the triangle law.

The figure constructed in Fig. 16b is called a *force polygon* (or, generally speaking, a *vector polygon*). Thus, the geometrical sum, or the principal vector, of a set of forces is represented by the closing side of a force polygon constructed with the given forces as its sides (the *polygon law*).

In constructing a vector polygon, care should be taken to arrange all the component vectors in one sense along the periphery of the polygon, with vector R being drawn in the opposite sense.

If the force R found by constructing a force polygon is applied at point A of the body in Fig. 16a, it will replace the action of all the given forces: i.e., it is their resultant.

Fig. 16.

7. Resolution of Forces. To resolve a force into two or more components means to replace it by a force system whose resultant is the original force. This problem is indeterminate and can

Fig. 17.

be solved uniquely only if additional conditions are stated. Two cases are of particular interest:

1) Resolution of a Force Into Two Components of Given Direction. Consider the resolution of force F in Fig. 17 into two compo-

nents whose lines of action are parallel to AB and AD (the forces and the lines are coplanar). The task is to construct a par-

allelogram with force F as its diagonal and its sides respectively parallel to AB and AD . The problem is solved by drawing through the beginning and tip of F lines parallel to AB and AD . Forces P and Q are the respective components, as $P + Q = F$.

The resolution can also be carried out by applying the triangle law (Fig. 17b). For this, the force F is laid off from an arbitrary point and lines parallel to AB and AD are drawn through its initial and terminal points to their point of intersection. Forces P and Q replace F if applied at point A or at any other point along the line of action of F .

2) Resolution of a Force Into Three Components of Given Direction. If the given directions are not coplanar the problem is determinate and is reduced to the construction of a parallelepiped with the given force F as its diagonal and its edges parallel to the given directions (see Fig. 15).

The student is invited to consider for himself the resolution of a given force F into two components P and Q coplanar with F if their magnitudes are given and $P + Q \geq F$. The problem has two solutions.

Solution of Problems. The method of resolution of forces is useful in determining the pressure on constraints induced by applied forces. Loads acting on rigid constraints are determined by resolving the given forces along the directions of the reactions of the constraints as, according to the 4th principle, a force acting on a constraint and its reaction have the same line of action. It follows, then, that this method can be applied only if the *directions* of the reactions of the respective constraints are immediately apparent.

Problem 1. Members AC and BC of the bracket in Fig. 18a are joined together and attached to the wall with pins. Neglecting the weight of the members, determine the thrust in BC if the suspended load weighs P , $\angle BAC = 90^\circ$, and $\angle ABC = \alpha$.

Solution. Force P acts on both members, and the reactions are directed along them. The unknown thrust is determined by applying force P at point C and resolving it along AB and BC . Component S_1 is the required force. From triangle CDE we obtain:

$$S_1 = \frac{P}{\cos \alpha}.$$

From the same triangle we find that member AC is under a tension of

$$S_2 = P \tan \alpha.$$

The larger the angle α , the greater the load on both members, which increases rapidly as α approaches 90° . For example, at $P = 100$ kg and $\alpha = 85^\circ$, $S_1 \approx 1,150$ kg and $S_2 \approx 1,140$ kg. Thus, to lessen the load angle α should be made smaller.

We see from these results that a small applied force can cause very large stresses in structural elements (see also Problem 2). The reason for this is that

forces are compounded and resolved according to the parallelogram law: a diagonal of a parallelogram can be very much smaller than its sides. If, therefore, in solving a problem you find that the loads or reactions seem too big as compared with the applied forces, this does not necessarily mean that your solution is wrong.

Finally, beware of a mistake frequently made in applying the method of force resolution. In Problem 1 we have to determine the force of thrust

Fig. 18.

acting on member BC . If we were to apply force P at C (Fig. 18b) and resolve it into a component Q_1 along BC and a component Q_2 perpendicular to it, we should obtain:

$$Q_1 = P \cos \alpha, \quad Q_2 = P \sin \alpha.$$

Although force P was resolved according to the rule, component Q_1 is not the required force acting on BC because not all of force Q_2 acts on AC . Actually force Q_2 acts on both members and, consequently, it increases the load acting on BC and adds to Q_1 .

This example shows that if a force is not resolved along the reactions of the respective constraints the required result cannot be obtained.

Problem 2. A lamp of weight $P = 20$ kg (Fig. 19) hangs from two cables AC and BC forming equal angles $\alpha = 5^\circ$ with the horizontal. Determine the tensions in the cables.

Solution. Resolve force P applied at C into components directed along the cables. The force parallelogram in this case is a rhombus whose diagonals are mutually perpendicular and bisecting. From triangle aCb we obtain

$$\frac{P}{2} = T_1 \sin \alpha,$$

whence

$$T_1 = T_2 = \frac{P}{2 \sin \alpha} \approx 115 \text{ kg.}$$

Fig. 19.

The equation shows that the smaller the angle α the greater the tension in the cables (for instance, at $\alpha = 1^\circ$, $T \approx 573$ kg). Should we attempt to stretch the cable absolutely horizontally it would break, for, at $\alpha \rightarrow 0$, $T \rightarrow \infty$.

Problem 3. Neglecting the weight of rod AB and crank OB of the reciprocating gear in Fig. 20, determine the circumferential force at B and the load on axle O of the crank caused by the action of force P applied to piston A if the known angles are α and β .

Solution. In order to determine the required forces we have to know the force Q with which the connecting rod AB acts on pin B . The magnitude

of Q can be found by resolving force P along AB and AD (AD being the direction in which piston A acts on the slides). Thus we obtain:

$$Q = \frac{P}{\cos \alpha}.$$

Transferring force Q to point B and resolving it as shown in Fig. 20 into the circumferential force F and the load R on the axle, we obtain:

$$F = Q \sin \gamma, \quad R = Q \cos \gamma.$$

Angle γ is an external angle of triangle OBA and equals $\alpha + \beta$. Hence, we finally obtain:

$$F = P \frac{\sin(\alpha + \beta)}{\cos \alpha}, \quad R = P \frac{\cos(\alpha + \beta)}{\cos \alpha}.$$

As $\alpha + \beta \leq 180^\circ$ and $\alpha < 90^\circ$, force F is always greater than zero, i.e., it is always directed as shown in the diagram. Force R , however, is directed from B to O only as long as $\alpha + \beta < 90^\circ$; at $\alpha + \beta > 90^\circ$, R reverses its sense. At $\alpha + \beta = 90^\circ$, $R = 0$.

Fig. 20.

This example shows that the method of force resolution can be employed even if the forces act on a body which is not in equilibrium. In such cases the load on a constraint is determined by resolving the applied force along the reaction of the constraint and the direction of the displacement of the point at which the force is applied (point B in Fig. 20). The pressure on a constraint, as determined by this method, is called a *static load*, as in calculating it the masses, velocities and accelerations of moving bodies are not taken into account. In actual physical situations such calculations can be employed only if the velocities and accelerations are small. If the masses, velocities and accelerations of the moving bodies are taken into account, the determined forces are called *dynamic loads* and are calculated by the methods of dynamics (§ 161).

8. Projection of a Force on an Axis and on a Plane. Let us now discuss analytical (mathematical) methods of solving problems of statics. These methods are based on the concept of the projection of a force on an axis.

The projection of a force on an axis is a scalar quantity, which is the product of the magnitude of the force and the cosine of the

angle between the direction of the force and the positive direction of the axis. It follows from this definition that the projections of a given force on any parallel axes of same sense are equal. This is useful in calculating the projection of a force on an axis not coplanar with that force. We shall denote the projection of a force F on an axis Ox by the symbol F_x . For the forces in Fig. 21 we have*:

$$F_x = F \cos \alpha, \quad Q_x = Q \cos \alpha_1 = -Q \cos \varphi. \quad (4)$$

It is apparent that the projection of a force on an axis is positive if the angle between the direction of the force and the

Fig. 21.

positive direction of the axis is acute, and negative if the angle is obtuse; if the force is perpendicular to the axis its projection is zero.

The diagram shows that the projection of a force on an axis is equal to the length of the line segment between the projections of its ends taken with the appropriate sign ($F_x = AB_1 = ab$, $Q_x = -D_1E = -de$).

The projection of a force F on a plane Oxy is a vector $F_{xy} = \overline{OB_1}$, comprised between the projections of the initial and terminal points of the force F on the plane (Fig. 22). Thus, unlike the projection of a force on an axis, the projection of a force on a plane is a vector quantity characterised by both magnitude and direction in that plane. The magnitude of the projection is $F_{xy} = F \cos \theta$, where θ is the angle between the direction of force F and its projection F_{xy} .

In some cases it may prove easier to find the projection of a force on an axis by first finding its projection on a plane

Fig. 22.

* The positive direction of an axis shall be taken to mean the direction from point O (the origin) towards the letter x denoting the given axis. We shall use arrowheads in diagrams only to show the direction of vectors.

through that axis. Thus, in the case shown in Fig. 22 we find that

$$F_x = F_{xy} \cos \varphi = F \cos \theta \cos \varphi, \quad F_y = F_{xy} \sin \varphi = F \cos \theta \sin \varphi.$$

9. Analytical Method of Defining a Force. For the analytical definition of a force we select a system of coordinate axes $Oxyz$ as a frame of reference for defining the direction of our force in space. In mechanics right-hand coordinate systems are usually

Fig. 23.

employed, i.e., systems in which a counterclockwise rotation about Oz carries Ox into Oy by the shortest way (Fig. 23). We can construct the vector denoting force F , if we know the magnitude of the force F and the angles α , β , γ it makes with the coordinate axes. The quantities F , α , β , γ define the given force F . The point A at which the force is applied must be defined additionally by its coordinates x , y , z .

For the solution of problems of statics it is often more convenient to define a force by its projections or by its rectangular components parallel to the coordinate axes, which are in fact its projections on those axes. Let us show that force F is completely defined if its projections F_x , F_y , F_z on the axes of a cartesian coordinate system are known. From formula (4), we have

$$F_x = F \cos \alpha, \quad F_y = F \cos \beta, \quad F_z = F \cos \gamma.$$

Squaring through and adding these equations, we obtain $F_x^2 + F_y^2 + F_z^2 = F^2$, since $\cos^2 \alpha + \cos^2 \beta + \cos^2 \gamma = 1$, whence,

$$\left. \begin{aligned} F &= \sqrt{F_x^2 + F_y^2 + F_z^2} \\ \cos \alpha &= \frac{F_x}{F}, \quad \cos \beta = \frac{F_y}{F}, \quad \cos \gamma = \frac{F_z}{F} \end{aligned} \right\} \quad (5)$$

Eqs. (5) give the magnitude of a force and the angles it makes with the coordinate axes in terms of its projections on the given axes, i.e., they define the force. It should be noted that in the first equation the sign before the radical is always positive as the formula gives only the *magnitude* of the force, and not its direction.

If the initial point of a force F is not at the origin of a coordinate system, its rectangular components F_x , F_y , F_z resolved parallel to the axes are equal in magnitude to the projections

of the force on the respective axes (see Fig. 23). It follows then that the vector of a force can be constructed geometrically according to the parallelepiped rule if its rectangular components or projections on the axes of a coordinate system are known.

If a set of given forces is coplanar, each force can be defined by its projections on two coordinate axes Ox and Oy . Then Eqs. (5) take the form:

$$F = \sqrt{F_x^2 + F_y^2}, \quad \cos \alpha = \frac{F_x}{F}, \quad \cos \beta = \frac{F_y}{F}. \quad (6)$$

The force can be constructed graphically according to its x and y components or projections by the parallelogram law.

10. Analytical Method for the Composition of Forces. Operations with vectors can be expressed in terms of operations with their projections by the following geometrical theorem: *The projection of the vector of a sum on an axis is equal to the algebraic sum of the projections of the component vectors on the same axis.* For if $s = a_1 + a_2 + a_3 + a_4$ (Fig. 24), then

$$a_{1x} = ab, \quad a_{2x} = bc, \quad a_{3x} = cd, \\ a_{4x} = -de; \quad s_x = ae$$

Fig. 24.

and, adding the first four equalities, we obtain, as could be expected from the diagram, that

$$a_{1x} + a_{2x} + a_{3x} + a_{4x} = ae = s_x,$$

which proves the theorem. With any number of components we have:

$$\text{if } s = \sum a_k, \text{ then } s_x = \sum a_{kx}. \quad (7)$$

Now consider the composition of forces. Take a system of forces F_1, F_2, \dots, F_n defined by their projections and denote the sum (the principal vector) of these forces by the symbol R ($R = \sum F_k$). It follows, then, by Eqs. (7) that

$$R_x = \sum F_{kx}, \quad R_y = \sum F_{ky}, \quad R_z = \sum F_{kz}. \quad (8)$$

Knowing R_x, R_y , and R_z we have from Eqs. (5)

$$\left. \begin{aligned} R &= \sqrt{R_x^2 + R_y^2 + R_z^2} \\ \cos \alpha &= \frac{R_x}{R}, \quad \cos \beta = \frac{R_y}{R}, \quad \cos \gamma = \frac{R_z}{R} \end{aligned} \right\} \quad (9)$$

Eqs. (8) and (9) provide an analytical solution for the problem of the composition of forces.

For coplanar forces the respective equations are

$$\left. \begin{aligned} R_x &= \sum F_{kx}, & R_y &= \sum F_{ky}; \\ R &= \sqrt{R_x^2 + R_y^2}, & \cos \alpha &= \frac{R_x}{R}, & \cos \beta &= \frac{R_y}{R}. \end{aligned} \right\} \quad (10)$$

If the forces are defined by their scalar magnitudes and their angles with the coordinate axes, it is first necessary to determine their projections on the coordinate axes.

Problem 4. Determine the sum of three forces P , Q , F whose respective projections are:

$$\begin{aligned} P_x &= 6 \text{ kg}, & P_y &= 3 \text{ kg}, & P_z &= 12 \text{ kg}; \\ Q_x &= 3 \text{ kg}, & Q_y &= -7 \text{ kg}, & Q_z &= 1 \text{ kg}; \\ F_x &= 5 \text{ kg}, & F_y &= 2 \text{ kg}, & F_z &= -8 \text{ kg}. \end{aligned}$$

Solution. From Eqs. (8) we find $R_x = 6 + 3 + 5 = 14$ kg; $R_y = 3 - 7 + 2 = -2$ kg; $R_z = 12 + 1 - 8 = 5$ kg. Substituting these quantities in Eqs. (9) we obtain:

$$R = \sqrt{14^2 + (-2)^2 + 5^2} = 15 \text{ kg}; \quad \cos \alpha = \frac{14}{15}; \quad \cos \beta = -\frac{2}{15}; \quad \cos \gamma = \frac{1}{3},$$

and finally: $R = 15$ kg, $\alpha = 21^\circ$, $\beta = 97^\circ 40'$, $\gamma = 70^\circ 30'$.

Problem 5. Determine the resultant of the three coplanar forces in Fig. 25a if $F = 17.32$ kg, $T = 10$ kg, $P = 24$ kg, $\varphi = 30^\circ$, $\psi = 60^\circ$.

Solution. Compute the projections of the given forces: $F_x = F \cos \varphi = 15$ kg; $T_x = -T \cos \psi = -5$ kg, $P_x = 0$; $F_y = -F \sin \varphi = -8.66$ kg; $T_y = T \sin \psi = 8.66$ kg; $P_y = -P = -24$ kg. Then, by Eqs. (10), $R_x = 15 - 5 = 10$ kg, $R_y = -8.66 + 8.66 - 24 = -24$ kg, whence

$$R = \sqrt{10^2 + (-24)^2} = 26 \text{ kg}; \quad \cos \alpha = \frac{10}{26} = \frac{5}{13}, \quad \cos \beta = -\frac{12}{13},$$

and finally:

$$R = 26 \text{ kg}, \quad \alpha = 67^\circ 20', \quad \beta = 157^\circ 20'.$$

Fig. 25.

To solve the problem graphically, choose a scale (e.g., 1 cm corresponds to 10 kg) and construct a force polygon with forces P , F , and T as its sides (Fig. 25b). Side ad represents to scale the direction and magnitude of the resultant R . If on measuring we find that $ad \approx 25$ cm, then $R \approx 25$ kg, with an error of 4% to the exact solution.

11. Equilibrium of a System of Concurrent Forces. It follows from the laws of mechanics that a rigid body subjected to the action of an external set of mutually balanced forces can either be at rest or in motion. We shall call this kind of motion "motion under no forces", "inertial" or "coasting" motion, of which uniform rectilinear translatory motion is an example.

From this we derive the important conclusion that *forces acting on bodies at rest and on bodies in inertial motion*

equally satisfy the conditions of equilibrium treated of in statics (see Problem 6). It is also obvious that the equilibrium of forces acting on a free rigid body is a necessary but insufficient condition for the equilibrium (rest) of the body. The body will remain at rest only if it was at rest before the moment when the balanced forces were applied.

For a system of concurrent forces acting on a body to be in equilibrium it is necessary and sufficient for the resultant of the forces to be zero. The conditions which the forces themselves must satisfy can be expressed in either graphical or analytical form.

1) Graphical Conditions of Equilibrium. Since the resultant R of a system of concurrent forces is defined as the closing side of a force polygon constructed with the given forces, it follows that R can be zero only if the terminal point of the last force of the polygon coincides with the initial point of the first force, i.e., if the polygon is closed.

Thus, for a system of concurrent forces to be in equilibrium it is necessary and sufficient for the force polygon drawn with these forces to be closed.

2) Analytical Conditions of Equilibrium. Analytically the resultant of a system of concurrent forces is determined by the formula

$$R = \sqrt{R_x^2 + R_y^2 + R_z^2}.$$

As the expression under the radical is a sum of positive components, R can be zero only if simultaneously $R_x = 0$, $R_y = 0$, $R_z = 0$, which follows from Eqs. (8), i.e., when the forces acting on the body satisfy the equations

$$\sum F_{kx} = 0, \quad \sum F_{ky} = 0, \quad \sum F_{kz} = 0. \quad (11)$$

Eqs. (11) express the conditions of equilibrium in analytical form: *The necessary and sufficient condition for the equilibrium of a three-dimensional system of concurrent forces is that the sums of the projections of all the forces on each of three coordinate axes must separately vanish.*

If all the concurrent forces acting on a body lie in one plane, they form a coplanar system of concurrent forces. Obviously, for such a force system only two equations are required to express the conditions of equilibrium:

$$\sum F_{kx} = 0, \quad \sum F_{ky} = 0. \quad (12)$$

Eqs. (11) and (12) also express the necessary conditions (or equations) of equilibrium of a free rigid body subjected to the action of concurrent forces.

3) **The Theorem of Three Forces.** The following theorem will often be found useful in solving problems of statics: *If a free rigid body remains in equilibrium under the action of three nonparallel coplanar forces, the lines of action of those forces intersect at one point.*

To prove the theorem, first draw two of the forces acting on the body, say F_1 and F_2 . As the theorem states that the forces

Fig. 26.

are not parallel and lie in the same plane, their lines of action intersect at some point A (Fig. 26). Now attach forces F_1 and F_2 to point A and replace them by their resultant R . Two forces will be acting on the body: R and F_3 , which is applied at some point B of the body. If the body is to be in equilibrium, then, according to the 1st principle, forces R and F_3 must be directed along the same line, i.e., along AB . Consequently, force

F_3 also passes through A , and the theorem is proved.

It should be noted that the reverse is not true, i.e., if the action lines of three forces intersect at one point, the body on which they are acting is not necessarily in equilibrium. Thus, the theorem expresses a *necessary, but not sufficient*, condition for the equilibrium of a free rigid body acted upon by three forces.

Example. Consider a beam AB (Fig. 27) hinged at A and reclining on a ledge at D . By replacing the constraints with their reactions we can treat the beam as a free body in equilibrium under the action of three forces. The lines of action of two of them, P and N_D , are known, and they intersect at K . Consequently, the reaction R_A of the hinge applied at A must also pass through K , i.e., it is directed along AK . In this case the theorem of three forces has helped us to determine the unknown direction of the reaction of hinge A .

Fig. 27.

12. Problems Statically Determinate and Statically Indeterminate. In problems where the equilibrium of constrained rigid bodies is considered, the reactions of the constraints are unknown quantities. Their number depends on the number and type of the constraints. A problem of statics can be solved only if the number of unknown reactions is not greater than the number of equilibrium equations in which they are present. Such problems are

called *statically determinate*, and the corresponding systems of bodies are called *statically determinate systems*.

Problems in which the number of unknown reactions of the constraints is greater than the number of equilibrium equations in which they are present are called *statically indeterminate*, and the corresponding systems of bodies are called *statically indeterminate systems*.

An example of a statically indeterminate system is a weight hanging from three strings lying in one plane (Fig. 28). There are three unknown quantities in this problem (the tensions T_1 , T_2 , T_3 of the strings), but only the two equations (12) for the equilibrium of a coplanar system of concurrent forces.

It can be seen that the static indeterminateness of a problem is a result of the presence of too many constraints. In the present case two strings are sufficient to keep the weight in equilibrium at any values of angles α and β (see Problem 2, Fig. 19), and the third string is redundant.

Fig. 28.

We shall be concerned only with statically determinate problems, i.e., problems in which the number of reactions is the same as the number of equilibrium equations involving them. For the solution of statically indeterminate problems the assumption of the rigidity of the bodies under consideration must be given up and their deformations taken into account. Problems of this kind are solved in the courses of strength of materials and statics of structures.

13. Solution of Problems of Statics. The solution of problems of statics involves the determination of loads acting on supports and stresses appearing in structural elements in conditions of equilibrium, as well as the determination of the general conditions of equilibrium of a structure not rigidly constrained.

In the simplest cases such problems can be solved by the method of force resolution (§ 7). Usually, however, a more general method of solution is applied, which is based on the examination of the conditions of equilibrium of a body acted upon by unknown forces or their equivalents. Any structure is actually an association of several connected bodies. Hence, in proceeding with the solution of a problem by this method it is necessary to isolate the *specific body whose equilibrium should be examined in order to obtain the unknown quantities*.

The solution consists of the following steps:

1. Choose the body whose equilibrium should be examined. For the problem to lend itself to solution, the given and required forces, or their equivalents, should all be applied to the body whose equilibrium is being examined (for instance, if the problem is to determine a load acting on a support, we can examine the equilibrium of the body experiencing the reaction of the support, which is equal in magnitude to the required load).

If the given forces act on one body and the required on another, it may be necessary to examine the equilibrium of each body separately, or even of some intermediary bodies as well.

2. Isolate the body from its constraints and draw the given forces and the reactions of the removed constraints. Such a drawing is called a free-body diagram and is drawn separately, as in Fig. 12b*. In drawing the reactions, the points brought up in § 4 in connection with the reactions of constraints should be taken into account.

3. State the conditions of equilibrium. The statement of these conditions depends on the force system acting on the free body and the method of solution (graphical or analytical). Special cases of stating the equilibrium conditions for different force systems will be examined in the respective chapters of this course.

4. Determine the unknown quantities, verify the answer and analyse the results. In solving a problem it is important to have a carefully drawn diagram, which helps to choose the correct method of solution and prevents errors in stating the conditions of equilibrium. All computations should be carried out in strict order.

The computations should, as a rule, be written out in general (algebraic) form. This provides formulas for determining the unknown quantities which can then be used to analyse the results. Solution in general form also makes it possible to catch mistakes by checking the dimensions (the dimensions of the terms in each side of an equation should be the same). If the problem is solved in general form, the numerical values should be substituted in the final equations.

In this section we shall discuss equilibrium problems involving concurrent forces. They can be solved by either the graphical or the analytical method.

* When sufficient experience is gained, the student may mentally isolate the body he is examining and draw the given forces and the reactions of the constraints acting on the body (and on it alone) on the general diagram (as in Fig. 31). However, if the equilibrium of two or more structural elements has to be examined, it is best to draw a free-body diagram.

a) The graphical method is suitable when the total number of given and required forces acting on a body is three. If the body is in equilibrium the force triangle must be closed (the construction should start with the known force). By solving the triangle trigonometrically we obtain the unknown quantities.

b) The analytical method can be applied for any number of forces. Before writing the conditions of equilibrium—which for a coplanar system of concurrent forces will be in the form of the two Eqs. (12), and for a three-dimensional system, the three Eqs. (11)—the coordinate axes must be chosen. The choice is arbitrary, but the equations can be simplified by taking one of the axes perpendicular to an unknown force. The beginner is advised to commence his solution by determining the projections of all the forces on each of the coordinate axes and tabulating the information (see Problems 6, 10, and 11).

Other suggestions are offered in the sample problems below.

Problem 6. A load of weight P lies on a plane inclined at α degrees to the horizontal (Fig. 29a). Determine the magnitude of the force F parallel to the plane which should be applied to the load to keep it in equilibrium, and the pressure Q exerted by the load on the plane.

Solution. The required forces act on different bodies: F on the load, and Q on the plane. To solve the problem we shall determine instead of Q the reaction N of the plane, which is equal to Q in magnitude and opposite in sense. In this case the given force P and the required forces F and N all act on the load, i.e., on one body. Now consider the equilibrium of the load as a free body (Fig. 29b),

Fig. 29.

with the applied forces P and F and the reaction N of the constraint (the plane). The required forces can be determined by employing either the graphical or the analytical method of stating the equilibrium conditions of the body.

Graphical solution. If the body is in equilibrium, the force triangle with P , F , and N as its sides must be closed. Start the construction with the given force: from an arbitrary point a lay off to scale force P (Fig. 29c). Through its initial and terminal points draw straight lines parallel to the directions of the forces F and N . The intersection of the lines gives us the third vertex c of the closed force triangle abc , whose sides bc and ca denote the required forces in the chosen scale. The direction of the forces is determined by the arrow rule: as the resultant is zero, no two arrowheads can meet in any vertex of the triangle.

The magnitudes of the required forces can also be computed (in which case the diagram need not be drawn to scale). Observing that angle $\angle abc = \alpha$, we have

$$F = P \sin \alpha, \quad N = P \cos \alpha.$$

Analytical method. Since the force system is coplanar, only two coordinate axes are needed. To simplify the computation, take axis Ox perpendicular to the unknown force N . Compute the projections of all the forces on each of the coordinate axes and tabulate the information*:

F_k	P	F	N
F_{kx}	$P \sin \alpha$	$-F$	0
F_{ky}	$-P \cos \alpha$	0	N

From Eqs. (12) we obtain:

$$\begin{aligned} P \sin \alpha - F &= 0, \\ -P \cos \alpha + N &= 0, \end{aligned}$$

which give:

$$F = P \sin \alpha, \quad N = P \cos \alpha.$$

The force exerted by the load on the plane is equal in magnitude to the calculated force $N = P \cos \alpha$ and opposite in sense.

It will be noted that the force F needed to hold the load on the inclined plane is less than its weight P . Thus, an inclined plane represents a simple machine which makes it possible to balance a large force with a smaller one.

As was shown in the beginning of § 11, these results hold equally good for a body at rest or in motion "under no forces". It follows, then, that in order to push the load with uniform velocity up a smooth surface the same force $F = P \sin \alpha$ has to be applied which is needed to keep it in equilibrium; similarly, the same force $F = P \sin \alpha$ has to be applied to brake the load if we wish it to slide with uniform velocity down the plane. For either motion to take place the load must receive an initial velocity, otherwise the force $F = P \sin \alpha$ acting on it will keep it at rest. The force exerted on the plane will in all cases be $P \cos \alpha$.

A general conclusion can be drawn from the solution of the above problem: *In problems of statics solved by the equations of equilibrium, the forces exerted by a body on its constraints should be replaced by the reactions of the constraints acting on the body, which are equal in magnitude and opposite in sense to the applied forces.* In solving problems by the method of force resolution (§ 7) the forces exerted by the constraints are determined directly.

Problem 7. The rod AB in Fig. 30a is hinged to a fixed support at A . Attached to the rod at B is a load $P = 10$ kg and a string passing over a pulley at C with a load $Q = 14.1$ kg tied to the other end of the string. The axes of the pulley C and the pin A lie on the same vertical and $AC = AB$. Neglecting the weight of the rod and the diameter of the pulley, determine the angle α at which the system will be in equilibrium and the stress in the rod AB .

Solution. Consider the conditions for the equilibrium of rod AB , to which all the given and required forces are applied. Removing the constraints

* The table should be filled by vertical columns: first compute the x and y projections of P , then of F , etc. The use of tables reduces the possibility of mistakes in the equations. The beginner will find tables especially useful until he acquires the necessary experience in operating with force projections.

and treating the rod as a free body (Fig. 30*b*), draw the forces acting on it: the weight of the load P , the tension T in the string, and the reaction R_A of the hinge, which is directed along AB , since in the present case the rod can only be in tension or in compression (see § 4). If the friction of the rope on the pulley is neglected, the tension in the string can be regarded as uniform throughout its length, whence $T = Q$.

Fig. 30.

For the graphical method of solution, construct a closed force triangle abc with forces P , T , R_A as its sides (Fig. 30*c*) starting with force P . As triangles abc and ABC are similar, we have $ab = bc$ and $\angle abc = \alpha$. Hence, as $T = Q = 2P \sin \frac{\alpha}{2}$,

$$R_A = P \text{ and } \sin \frac{\alpha}{2} = \frac{Q}{2P}.$$

It follows from these results that at $\alpha < 180^\circ$ equilibrium is possible only if $Q < 2P$ and that the rod will be compressed with a force equal to P at any values of Q and α .

The case of $\alpha = 180^\circ$ should be examined separately. It is apparent that in this case equilibrium is possible at any values of P and Q . If $P > Q$ the rod will be stretched with a force $P - Q$; if $Q > P$ the rod will be compressed with a force $Q - P$.

Substituting the numerical values, we obtain $R_A = 10$ kg, $\alpha = 90^\circ$ (the rod is horizontal).

Note that force Q (the weight of the load) was not directly included in the equilibrium condition (in the force triangle), as it is applied to the load and not to the rod whose equilibrium was considered.

Further on in this book we shall not draw free-body diagrams, but in picturing the forces acting on a given body it should always be visualised as free, as in Figs 29*b*, 30*b*, and 12*b*.

Problem 8. A crane held in position by a journal bearing A and a thrust bearing B carries a load P (Fig. 31). Neglecting the weight of the structure, determine the reactions R_A and R_B of the constraints if the jib is of length l and $AB = h$.

Solution. Consider the equilibrium of the crane as a whole under the action of the given and required forces. Mentally remove the constraints A and B and draw the given force P and the reaction R_A of the journal bearing perpendicular to AB . The reaction R_B of the thrust bearing can have any direction in the plane of the diagram. But the crane is in equilibrium under the action

of three forces and consequently their lines of action must intersect in one point. This is point E , where the lines of action of P and R_A cross. Hence, the reaction R_B is directed along BE .

To solve the problem by the graphical method draw a closed triangle abc with forces P , R_A , R_B as its sides, starting with the given force P . From the similarity of triangles abc and ABE we obtain:

$$\frac{R_A}{P} = \frac{l}{h}, \quad \frac{R_B}{P} = \frac{\sqrt{h^2 + l^2}}{h},$$

whence

$$R_A = \frac{l}{h} P, \quad R_B = \sqrt{1 + \frac{l^2}{h^2}} P.$$

Fig. 31.

B are respectively equal in magnitude to R_A and R_B but opposite in sense. The greater the ratio $l:h$ the greater the load acting on the constraints.

This problem is an example of the application of the theorem of three forces.

Note the following conclusion arising from it: *If the statement of a problem gives the linear dimensions of structural elements, it is more convenient to solve the force triangle by the rule of similarity; if the angles are given (Problem 6), the formulas of trigonometry should be used.*

Problem 9. A horizontal force P is applied to hinge A of the toggle-press in Fig. 32a. Neglecting the weight of the rods and piston, determine the force exerted by the piston on body M when the given angles are α and β .

Solution. First consider the equilibrium of the hinge A to which the given force P is applied. Regarding the hinge as a free body, we find that also acting on it are the reactions R_1 and R_2 of the rods directed along them. Construct a force triangle (Fig. 32b). Its angles are $\varphi = 90^\circ - \alpha$, $\psi = 90^\circ - \beta$, $\gamma = \alpha + \beta$. By the law of sines we have:

$$\frac{R_1}{\sin \varphi} = \frac{P}{\sin \gamma}, \quad R_1 = \frac{P \cos \alpha}{\sin (\alpha + \beta)}.$$

Now consider the equilibrium of the piston, regarding it as a free body. Acting on it are three forces: $R'_1 = -R_1$ exerted by rod AB , the reaction N of the wall, and the reaction Q of the pressed body. The three forces are in equilibrium, consequently they are concurrent. Constructing a triangle with the forces as its sides (Fig. 32c), we find:

$$Q = R'_1 \cos \beta.$$

Substituting for R'_1 its equivalent R_1 , we finally obtain:

$$Q = \frac{P \cos \alpha \cos \beta}{\sin (\alpha + \beta)} = \frac{P}{\tan \alpha + \tan \beta}.$$

Fig. 32.

The force with which the piston compresses the body M is equal to Q in magnitude and opposite in sense.

From the last formula we see that with a constant applied force P the pressure Q increases as the angles α and β diminish.

If the rods OA and AB are of equal length, then $\alpha = \beta$ and $Q = 0.5 P \cot \alpha$.

The following conclusion can be drawn from this solution: *In some problems the given force or forces are applied to one body and the required force or forces act on another; in such cases the equilibrium of the first body is considered and the force with which it acts on the other body is found; then the second body is examined and the required quantities are obtained.*

Fig. 33.

Problem 10. Rods AB and BC of the bracket in Fig. 33a are joined together and attached to the wall by hinges. Over the pulley at B passes a string one end of which is fastened to the wall while the other supports a load of weight Q . Neglecting the weight of the rods and the diameter of the pulley, determine the reactions of the rods if angles α and β are given.

Solution. Consider the equilibrium of the pulley with the section DE of the string which is in contact with it*. Isolate the body and draw the reactions of the constraints (Fig. 33b). Acting on the pulley and the segment of the string passing over it are four external forces: the tension Q in the right-hand part of the string, the tension T in the left-hand part of the string, which is equal to Q in magnitude ($T = Q$), and the reactions R_1 and R_2 of the rods directed along the rods. Neglecting the diameter of the pulley, the forces can be treated as concurrent. As there are more than three forces the analytical method of solution is more convenient. Draw the coordinate axes as shown in the diagram and compute the x and y projections of all the forces:

* In such cases it is best to treat the pulley as one body together with the section of the string with which it is in contact. The unknown reciprocal actions of the cable and the pulley distributed along arc de constitute a system of balanced internal forces and do not enter into the equilibrium conditions (see § 3, corollary of the 4th principle). Should we treat the pulley separately (Fig. 33c, in a larger scale) we would have to consider the forces exerted by the thread on the pulley along the arc de , the resultant of which would have to be found by additionally examining the conditions of equilibrium of section DE of the thread (applying the principle of solidification). This would make the calculations much more involved.

F_k	Q	T	R_1	R_2
F_{kx}	0	$-T \cos \beta$	$R_1 \sin \alpha$	$-R_2$
F_{ky}	$-Q$	$T \sin \beta$	$R_1 \cos \alpha$	0

Now apply the formulas of equilibrium (12) and write the corresponding equations, substituting for T the equal quantity Q :

$$\begin{aligned} -Q \cos \beta + R_1 \sin \alpha - R_2 &= 0 \\ -Q + Q \sin \beta + R_1 \cos \alpha &= 0. \end{aligned}$$

From the second equation we find:

$$R_1 = \frac{1 - \sin \beta}{\cos \alpha} Q.$$

Substituting this value of R_1 into the first equation and transposing, we obtain:

$$R_2 = Q \frac{\sin \alpha - \cos (\alpha - \beta)}{\cos \alpha}.$$

It follows from the expression of R_1 that at any acute angles α and β , $R_1 > 0$. This means that the reaction R_1 is always directed as shown in the diagram. The force which the pulley exerts on the rod is directed in the opposite direction (rod BC is under thrust). For R_2 we obtain a different result. Let us assume that angles α and β are always acute. Since

$$\sin \alpha - \cos (\alpha - \beta) = \sin \alpha - \sin (90^\circ - \alpha + \beta),$$

the difference is positive if $\alpha > (90^\circ - \alpha + \beta)$ or if $2\alpha > 90^\circ + \beta$. Hence, at $\alpha > \left(45^\circ + \frac{\beta}{2}\right)$, $R_2 > 0$, i.e., the reaction R_2 is directed as shown in the diagram. But if $\alpha < \left(45^\circ + \frac{\beta}{2}\right)$, $R_2 < 0$, and the reaction R_2 is of opposite sense and is directed from A to B . In the first case rod AB is in tension, in the second it is in compression. At $\alpha = 45^\circ + \frac{\beta}{2}$, $R_2 = 0$.

The following conclusions are important: 1) If a system includes pulleys with strings passing over them, in writing the equations of equilibrium *a pulley and the section of the cable with which it is in contact should be treated as a single body*. If the friction of the cable on the pulley or the friction of the pulley axle can be neglected, *the tension in both portions of the string is equal in magnitude and directed away from the pulley*—otherwise the string would slip in the direction of the greater tension or the pulley would turn (see also Problem 13).

2) If, in drawing the reactions of constraints, any reaction is pointed in the wrong direction, this will show up immediately in the force polygon of a graphical solution (the arrowhead rule); in an analytical solution the sign of the respective reaction will be negative.

Whenever possible, however, the forces should be directed correctly. In Problem 8, for instance, the direction of the reaction of bearing A can be determined by the following consideration: if the bearing is removed, force P will tend to overturn the crane to the right, consequently, force R_A , which replaces

the action of the bearing, should be directed to the left in order to keep the crane in equilibrium.

Problem 11. The vertical pole OA in Fig. 34 is anchored down by guy wires AB and AD which make equal angles $\alpha = 30^\circ$ with the pole; the angle between the planes AOB and AOD is $\varphi = 60^\circ$. Two horizontal wires parallel to the axes Ox and Oy are attached to the pole, and the tension in each of them is $P = 100$ kg. Neglecting the weight of all the elements, determine the vertical load acting on the pole and the tensions in the guy wires.

Solution. Consider the equilibrium of point A to which the guys and horizontal wires are attached. Acting on it are the reactions P_1 and P_2 of the horizontal wires ($P_1 = P_2 = P$), the reactions R_2 and R_3 of the guys, and the reaction R_1 of the pole. The force system is three-dimensional, and the analytical method of solution is most suitable. Draw a coordinate system as shown in the diagram, compute the projections of all the forces on each of the axes, and tabulate the information (the x and y projections of R_3 are calculated as explained at the end of § 8):

Fig. 34

F_k	P_1	P_2	R_1	R_2	R_3
F_{kx}	0	$-P$	0	0	$R_3 \sin \alpha \sin \varphi$
F_{ky}	$-P$	0	0	$R_2 \sin \alpha$	$R_3 \sin \alpha \cos \varphi$
F_{kz}	0	0	R_1	$-R_2 \cos \alpha$	$-R_3 \cos \alpha$

From the equilibrium Eqs. (11) we have:

$$\begin{aligned} -P + R_3 \sin \alpha \sin \varphi &= 0, \\ -P + R_2 \sin \alpha + R_3 \sin \alpha \cos \varphi &= 0, \\ R_1 - R_2 \cos \alpha - R_3 \cos \alpha &= 0, \end{aligned}$$

solving which we obtain:

$$R_3 = \frac{P}{\sin \alpha \sin \varphi}, \quad R_2 = P \frac{1 - \cot \varphi}{\sin \alpha}, \quad R_1 = P \left(1 + \tan \frac{\varphi}{2} \right) \cot \alpha.$$

The results show that at $\varphi < 45^\circ$, $R_2 < 0$, and the reaction R_2 is of opposite sense than shown in the diagram. As a wire cannot be in compression, it follows that the guy AD should be anchored in such a way that angle φ would be greater than 45° . Substituting the scalar quantities in the equations, we obtain:

$$R_3 = 231 \text{ kg}; \quad R_2 = 85 \text{ kg}; \quad R_1 = 273 \text{ kg}.$$

14. Moment of a Force About an Axis (or a Point). We know from experience that a force acting on a body tends either to displace it in some direction or to rotate it about a point.

The tendency of a force to turn a body about a point or an axis is called the *moment* of that force.

Consider a force \mathbf{F} applied at a point A of a rigid body (Fig. 35) which tends to rotate the body about a point O . The perpendicular distance h from O to the line of action of \mathbf{F} is called the

moment arm of force \mathbf{F} about the centre O . As the point of application of the force can be transferred arbitrarily along its line of action, it is apparent that the rotational action of any force depends only on 1) the magnitude of the force F and its moment arm h ; 2) the aspect of the plane of rotation through the centre O and

the force \mathbf{F} ; 3) the sense of the rotation in that plane.

For the present we shall limit ourselves to coplanar force systems, in which the plane of rotation is the same for all the forces and does not have to be specifically defined. The sense of rotation is denoted by $(+)$ or $(-)$, assuming it to be positive in some particular direction.

Thus we may formulate the concept of moment of a force as a measure of the tendency of the force to turn the body on which it acts: *The moment of a force \mathbf{F} about a centre O is defined as the product of the force magnitude and the length of the moment arm taken with appropriate sign.*

We shall denote the moment of a force \mathbf{F} about a centre O by the symbol $m_O(\mathbf{F})$. Thus,

$$m_O(\mathbf{F}) = \pm Fh. \quad (13)$$

We shall call a moment positive if the applied force tends to rotate the body counterclockwise, and negative if it tends to rotate the body clockwise. Thus, the sign of the moment of the force \mathbf{F} about O is $(+)$ in Fig. 35a, and $(-)$ in Fig. 35b. If the force is measured in kilograms and its perpendicular distance from the centre in metres, the dimension of the moment is *kilogram-metre* (kg-m).

Note the following properties of the moment of a force:

- 1) The moment of a force does not change if the point of application of the force is transferred along its line of action.
- 2) The moment of a force about a centre O can be zero only if the force is zero or if its line of action passes through O (i.e., the moment arm is zero).

Fig. 35.

3) The scalar magnitude of the moment of a force is represented by twice the area of the triangle OAB (Fig. 35b):

$$m_O(\mathbf{F}) = \pm 2 \text{ areas of } \triangle OAB. \quad (14)$$

This follows from the fact that

$$\text{area of } \triangle OAB = \frac{1}{2} AB \cdot h = \frac{1}{2} F \cdot h.$$

4) The moment of a force \mathbf{F} about a centre O defines a point on the line of action of the force at a distance from O :

$$h = \frac{|m_O(\mathbf{F})|}{F},$$

where h is laid off perpendicular to vector \mathbf{F} in the direction defined by the sign of the moment.

15. Varignon's Theorem of the Moment of a Resultant. *The moment of the resultant of a coplanar system of concurrent forces about any centre is equal to the algebraic sum of the moments of the component forces about that centre (Varignon's theorem*).*

Consider a coplanar system of concurrent forces $\mathbf{F}_1, \mathbf{F}_2, \dots, \mathbf{F}_n$ applied at the point A (Fig. 36). Denoting their resultant \mathbf{R} , take an arbitrary point O and draw axis Ox perpendicular to OA as shown. For any force of the system, \mathbf{F}_1 , for example, we have $m_O(\mathbf{F}_1) = 2 \text{ areas } \triangle OAB = OA \cdot Ob$, or

$$m_O(\mathbf{F}_1) = OA \cdot F_{1x}, \quad (15)$$

where $F_{1x} = Ob$ is the projection of force \mathbf{F}_1 on axis Ox .

Equation (15) is valid also when force \mathbf{F} passes below OA . In this case the moment will be negative, because the projection F_x will be negative.

To prove the theorem, note that $\mathbf{R} = \sum \mathbf{F}_k$. From the theorem of the projection of a sum of forces on an axis we have $R_x = \sum F_{kx}$. Multiplying through by OA we obtain:

$$OA \cdot R_x = \sum (OA \cdot F_{kx})$$

or, by Eq. (15),

$$m_O(\mathbf{R}) = \sum m_O(\mathbf{F}_k). \quad (16)$$

Eq. (16) is the mathematical expression of Varignon's theorem.

* Pierre Varignon (1654-1722), a celebrated French mathematician and mechanic, who outlined the fundamentals of statics in his book "Projet d'une nouvelle mécanique." (1687).

Fig. 36.

16. Equations of Moments of Concurrent Forces. The analytical conditions for the equilibrium of concurrent forces can be expressed in terms of either their projections or their moments. Let us demonstrate that the necessary and sufficient conditions for the equilibrium of a coplanar system of concurrent forces are:

$$\sum m_B(F_k) = 0, \quad \sum m_C(F_k) = 0, \quad (17)$$

where B and C are arbitrary points not collinear with the point A where the forces intersect (Fig. 37).

The necessity of these conditions is apparent since, for example, if $\sum m_B(F_k) \neq 0$ then, by Eq. (16), $m_B(R) \neq 0$, whence $R \neq 0$, and equilibrium is impossible.

Fig. 37.

Let us prove the sufficiency of these conditions. If the conditions (17) are fulfilled, then according to Varignon's theorem, $m_B(R) = 0$ and $m_C(R) = 0$, which is possible only if $R = 0$ or if the line of action of R passes through both B and C . The latter condition being impossible, as the resultant of the concurrent forces must pass through A (Fig. 37), which is stipulated as not collinear

with B and C . Thus, Eqs. (17) can be valid only if the resultant $R = 0$, i.e., if the force system is in equilibrium.

It is apparent that satisfaction of only one of the conditions (17) is insufficient for equilibrium.

In solving problems with Eqs. (17) the equations can be made to contain a single unknown quantity each by taking the centres of moments on the lines of action of the unknown forces.

Problem 12. Solve Problem 7 with the equations of moments.

Solution. Introducing the symbol $a = AB = AC$, take points A and C as the centres of the moments (Fig. 38). Drawing perpendiculars AE and AK from A to the lines of action of forces T and P , we obtain: $AE = a \cos \frac{\alpha}{2}$, $AK = a \sin \alpha$,

whence $m_A(T) = Ta \cos \frac{\alpha}{2}$, $m_A(P) = -Pa \sin \alpha$.

Furthermore, $m_A(R_A) = 0$. The moments of the forces about C are computed similarly. From the equilibrium Eqs. (17) we obtain:

Fig. 38.

$$\sum m_A(F_k) = Ta \cos \frac{\alpha}{2} - Pa \sin \alpha = 0,$$

$$\sum m_C(F_k) = R_A a \sin \alpha - Pa \sin \alpha = 0.$$

As $T=Q$, we obtain from the first equation:

$$\left(Q - 2P \sin \frac{\alpha}{2}\right) \cos \frac{\alpha}{2} = 0$$

whence angle α , which defines the position of equilibrium, has two values:

$$\alpha = 180^\circ \quad \text{and} \quad \sin \frac{\alpha}{2} = \frac{Q}{2P}.$$

From the second equation we find that at $\alpha \neq 180^\circ$, $R_A = P$.

Problem 13. In Problem 10 determine the reaction R_2 by means of the equations of moments.

Solution. Taking the moments about C (see Fig. 33b) and assuming $CB=a$, we obtain:

$$\sum m_C(F_k) = Ta \cos(\alpha - \beta) + R_2 a \cos \alpha - Qa \sin \alpha = 0,$$

whence, as $T=Q$, we immediately find:

$$R_2 = Q \frac{\sin \alpha - \cos(\alpha - \beta)}{\cos \alpha}.$$

The reaction R_1 can be found by taking the moments about A .

The equations of moments can thus also be used to verify answers obtained by other methods.

Note that the validity of the equality $T=Q$ can be verified by writing an equation of moments about the centre of the pulley (this equation, as will be proved in § 24, also holds good for non-concurrent forces). In this case we obtain $Tr - Qr = 0$, where r is the radius of the pulley, or $T=Q$.

Chapter 3

PARALLEL FORCES AND COUPLES IN A PLANE

17. Composition and Resolution of Parallel Forces. Let us find the resultant of two parallel forces acting on a rigid body. Two cases are possible: 1) the forces are of same sense, and 2) the forces are of opposite sense.

1) **Composition of Two Forces of Same Sense.** Consider a rigid body on which two parallel forces F_1 and F_2 are acting (Fig. 39). By applying the 1st and 2nd principles of statics we can replace the given system of parallel forces with an equivalent system of concurrent forces Q_1 and Q_2 . For this, apply two balanced forces P_1 and P_2 ($P_1 = -P_2$) directed along AB at points A and B , compound them with forces F_1 and F_2 according to the parallelogram law, transfer the resultants Q_1 and Q_2 to point O where their lines of action intersect, and resolve them into their initial components. As a result we have applied at point O two balanced forces P_1 and P_2 , which can be neglected, and the two forces F_1 and F_2 directed along the same line. Now transfer the

and point of application of the resultant is determined by Eqs. (20) and (21). Thus, the resultant of two parallel forces of opposite sense acting on a rigid body is equal in magnitude to the difference between their magnitudes, parallel to them, and has the same sense as the greater force; the line of action of the resultant lies on an extension of the line segment connecting the points of application of the component forces, its distances from the points being inversely proportional to the forces.

If several parallel forces act on a body, their resultant, if any, can be found by consecutively applying the rule of composition of two forces, or by a method which will be examined in Chapter 4.

3) Resolution of Forces. The above formulas can be used to solve problems on the resolution of a given force into two forces parallel to it and of same or opposite sense. The problem becomes determinate when additional conditions are given (e.g., the lines of action of both required forces or the magnitude and line of action of one of them).

Fig. 41.

Problem 14. Determine the forces exerted by the horizontal beam in Fig. 41 on the supports A and B if the weights lying on the beam are $P_1 = P_2 = 80$ kg and the weight of the beam is neglected.

Solution. First replace the forces P_1 and P_2 with their resultant $R = 160$ kg through point D . By resolving R along the directions of the reactions of the supports (see § 7), we obtain the required forces Q_1 and Q_2 exerted by the beam on the supports. From the equations

$$\frac{Q}{DB} = \frac{R}{AB} \quad \text{and} \quad Q_2 = R - Q_1$$

we find:

$$Q_1 = 100 \text{ kg}, \quad Q_2 = 60 \text{ kg}.$$

Fig. 42.

Problem 15. A beam AB of length $l = 2.5$ m passes through a wall of thickness $a = 0.5$ m (Fig. 42). Suspended from end B of the beam is a load of weight $P = 3$ t. Neglecting the weight of the beam, determine the forces acting on the wall, assuming them applied at points A and D .

Solution. Resolve force P into forces Q_D and Q_A along the reactions of the constraints D and A . As force P does not lie between the required forces, they must be of opposite sense, and Q_D , as being closer to P , is greater than Q_A and of the same sense as P . From the equations

$$\frac{Q_D}{l} = \frac{P}{a} \quad \text{and} \quad P = Q_D - Q_A$$

we obtain:

$$Q_D = \frac{l}{a} P = 15 \text{ t}, \quad Q_A = 12 \text{ t}.$$

The results can be verified by the proportion:

$$\frac{Q_A}{l-a} = \frac{P}{a}.$$

18. Force Couples. Moment of a Couple. A *couple* is a set of two parallel forces of same magnitude and opposite sense acting on a rigid body (Fig. 43). Clearly, a force system constituting a couple is not in equilibrium (see 1st principle). Furthermore,

Fig 43.

unlike previously examined systems, a couple has no resultant. For if, say, the couple in Fig. 43 had a resultant Q , the force system F, F' and $Q' = -Q$ would have to be in equilibrium, which is impossible because $F + F' + Q' \neq 0$ (as $F + F' = 0$, and $Q' \neq 0$). It will be shown later that for any system of forces to be in equilibrium their geometrical sum must be zero. Thus, a couple cannot be replaced or balanced by a single force. For this reason the

properties of the couple as a special mode of mechanical interaction between bodies are the subject of a special study.

The plane through the lines of action of both forces of a couple is called the *plane of action of the couple*. The perpendicular distance d between the lines of action of the forces is called the *arm of the couple*. The action of a couple on a rigid body is a tendency to turn it; it depends on: 1) the magnitude F of the forces of the couple and the perpendicular distance d between them; 2) the aspect of the plane of action of the couple, and 3) the sense of rotation in that plane. A couple is characterised by its *moment*. In this chapter we shall discuss the properties of couples of coplanar forces. For this case the following definition can be given in analogy with that of the moment of a force (§ 14): *The moment of a couple is defined as a quantity equal to the product of the magnitude of one of the forces of the couple and the perpendicular distance between the forces (the length of the moment arm) taken with the appropriate sign**. Denoting

* This concept should not be confused with the moment of a force. The concept of moment of a force presumes a point about which the moment is taken. The moment of a couple is defined only by its forces and the perpendicular distance between them: it is not associated with any point in the plane. The theory of couples was elaborated by the eminent French mathematician and geometrician Louis Poinsot (1777-1859).

the moment of a couple by the symbol m or M , we have:

$$m = \pm Fd. \quad (22)$$

The moment is said to be positive if the action of the couple tends to turn a body counterclockwise, and negative if clockwise. The dimension of the moment of a couple is the same as the moment of a force (kilogram-metre). It is apparent that the moment of a couple is equal to the moment of one of its forces about the point of application of the other (Fig. 43):

$$m = m_B F = m_A (F'). \quad (23)$$

Fig. 44.

Let us prove the following theorem of the moments of the forces of a couple: *The algebraic sum of the moments of the forces of a couple about any point in its plane of action is independent of the location of that point and is equal to the moment of the couple.* For, taking an arbitrary point O in the plane of a couple (Fig. 44), we find: $m_O(F) = -F \cdot Oa$, $m_O(F') = F' \cdot Ob$. Adding the two equations and noting that $F' = F$ and $Ob - Oa = d$, where d is the couple arm, we obtain:

$$m_O(F) + m_O(F') = m. \quad (24)$$

This theorem will be found useful in computing the moments of couples about any centre.

19. Equivalent Couples. Before stating the conditions necessary for two couples to be equivalent let us prove the following theorem: *A couple acting on a rigid body can be replaced by any other couple of the same moment lying in the same plane without altering the external effect on that body.* Let there be a couple (F, F') acting on a rigid body and let the perpendicular distance between its two forces be d_1 . Now apply the forces of the couple at arbitrary points A and B on their respective lines of action (Fig. 45), draw through the points two arbitrary parallel lines AD and BE and denote the distance between them d_2 . Resolve F along BA and AD into forces Q and P , and F' along AB and BE into forces Q' and P' . Obviously $P = -P'$ and $Q = -Q'$. Forces Q and Q' are balanced and can be discarded, and the couple (F, F') is replaced by the couple (P, P') with different force magnitude and couple arm. Forces Q and Q' can, obviously, be applied at any points D and E along their lines of action. Since points A and B and the directions of AD and BE are

arbitrary, the location of the couple (P, P') in the plane is also arbitrary. Let us now show that the moments of the two couples are equal. As force F is the resultant of forces P and Q , from Varignon's theorem

$$m_B(F) = m_B(P) + m_B(Q).$$

But $m_B(F) = Fd_1$, $m_B(P) = Pd_2$, and $m_B(Q) = 0$; consequently, $Fd_1 = Pd_2$, i.e., the moments of the two couples are equal, which proves the theorem.

Fig. 45.

The following properties of a couple follow from this theorem:

1) A couple can be transferred anywhere in its plane of action;

2) It is possible to change the magnitudes of the forces of a couple or the perpendicular distance between them arbitrarily without changing its moment.

It follows from these properties that two coplanar couples of equal moment are equivalent as, by performing the above operations they

can be transformed into one another. From the above theorems it is also apparent that the action of a couple on a rigid body really is characterised by its moment.

Hence, a couple in a given plane is completely defined by its moment; the magnitudes of the forces or the distance between them is immaterial. That is why in engineering problems a couple is often denoted by a semi-circular arrow indicating the direction of the rotation, without drawing the forces of the couple (Fig. 46, for example, shows a force F and a couple of moment m acting on the body).

Fig. 46.

Let us now prove another theorem: *The external effect of a couple on a rigid body remains the same if the couple is transferred from a given plane into any other parallel plane.*

Consider a couple (F, F') lying in plane I (Fig. 47). Now take a plane II parallel to the given plane, and in it a line DE equal and parallel to AB . At points D and E apply two pairs of balanced forces such that $F_1 = F_2 = F$ and $F'_1 = F'_2 = F'$. Note that $ABDE$ is a parallelogram the diagonals of which bisect at their point of intersection C . Compound now the parallel equal forces F and F_2 and replace them with their resultant $R = 2F$ applied at the middle of AE , i.e., at C . The resultant of forces F' and F'_2 is $R' = 2F' = R$ applied at the middle of BD , i.e., also at C , and forces R and R' therefore cancel each other.

As a result the couple (F, F') is replaced by a similar couple (F_1, F'_1) in plane II .

It follows from the above theorems that two couples of equal moment lying in parallel planes are equivalent.

Attention is drawn to the following analogy: A force acting on a rigid body is defined by its magnitude, line of action, and sense; its point of application can be transferred arbitrarily along the line of action. A couple acting on a rigid body is defined by the magnitude of its moment, its plane of action, and the sense of rotation; a couple can be situated anywhere in its plane of action.

Fig. 47.

Fig. 48.

The motion of a rigid body subjected to a couple is discussed in dynamics. It will be proved in theorems of dynamics that any couple acting on a free rigid body tends to turn that body about its centre of gravity (see p. 318). If a body has a fixed axis of rotation, the external effect (the turning moment or torque) of a couple acting in a plane perpendicular to that axis will be the same regardless of its location in the plane, which follows from Eq. (24).

Problem 16. The bracket $ABCD$ in Fig. 48 is in equilibrium under the action of two parallel forces P and P' making a couple. Determine the load on the supports if $AB = a = 15$ cm, $BC = b = 30$ cm, $CD = c = 20$ cm, and $P = P' = 30$ kg.

Solution. Replace couple (P, P') with an equivalent couple (Q, Q') whose two forces are directed along the reactions of the constraints. The moments of the two couples are equal, i.e., $P(c - a) = Qb$, consequently the loads on the constraints are:

$$Q = Q' = \frac{c - a}{b} P = 5 \text{ kg}$$

and are directed as shown in the diagram.

20. Composition of Coplanar Couples. Conditions for the Equilibrium of Couples. Let us prove the following theorem of the

composition of couples: *A system of coplanar couples is equivalent to a single couple lying in the same plane the moment of which equals the algebraic sum of the moments of the component couples.* Let three couples of moments m_1 , m_2 , and m_3 be acting on a body (Fig. 49). By the theorem of equivalent couples they can be replaced by couples (P_1, P'_1) , (P_2, P'_2) , and (P_3, P'_3) with a common arm d and of respectively same moments:

Fig. 49.

$$P_1 d = m_1, \quad -P_2 d = m_2, \quad P_3 d = m_3.$$

Compounding the forces applied at A and B respectively, we obtain a force R at B and a force R' at A the magnitudes of which are:

$$R = R' = P_1 - P_2 + P_3.$$

As a result the set of couples is replaced by a single couple (R, R') of moment

$$M = Rd = P_1 d + (-P_2 d) + P_3 d = m_1 + m_2 + m_3.$$

The theorem is proved for three couples, but apparently the same result can be obtained for any number of couples, and a set of n couples of moments m_1, m_2, \dots, m_n can be replaced by a single couple of moment

$$M = \sum m_k. \quad (25)$$

It follows from this theorem that for a coplanar system of couples to be in equilibrium it is necessary and sufficient for the algebraic sum of their moments to be zero:

$$\sum m_k = 0. \quad (26)$$

Problem 17. A couple of moment m_1 acts on gear 1 of radius r_1 in Fig. 50a. Determine the moment m_2 of the couple which should be applied to gear 2 of radius r_2 in order to keep the system in equilibrium.

Solution. Consider first the conditions for the equilibrium of gear 1. Acting on it is the couple of moment m_1 which can be balanced only by the action of another couple, in this case the couple (Q_1, R_1) created by the force Q_1 exerted on the tooth of gear 1 by gear 2, and the reaction R_1 of the axle A. From Eq. (26) we have $m_1 + (-Q_1 r_1) = 0$, or $Q_1 = m_1 / r_1$.

Consider now the conditions for the equilibrium of gear 2. By the 4th principle we know that gear 1 acts on gear 2 with a force $Q_2 = -Q_1$ (Fig. 50b), which together with the reaction of axle B makes a couple (Q_2, R_2) of moment $-Q_2 r_2$. This couple must be balanced by a couple of moment m_2 acting on gear 2; from Eq. (26) we have: $m_2 + (-Q_2 r_2) = 0$. Hence, as $Q_2 = Q_1$,

$$m_2 = \frac{r_2}{r_1} m_1.$$

It will be noticed that the couples of moments m_1 and m_2 do not satisfy the equilibrium condition in Eq. (26), which could be expected, as the couples are applied to *different* bodies.

Fig. 50.

The force Q_1 (or Q_2) obtained in the course of the solution is called the *circumferential force* acting on the gear. The circumferential force is thus equal to the moment of the acting couple divided by the radius of the gear:

$$Q_1 = \frac{m_1}{r_1} = \frac{m_2}{r_2}.$$

Chapter 4

GENERAL CASE OF FORCES IN A PLANE

21. Theorem of the Translation of a Force to a Parallel Position. Many problems of statics, including the one of reduction of a force system to the simplest possible form, can be solved with the following theorem: *A force acting on a rigid body can be moved parallel to its line of action to any point of the body, provided a couple is added of moment equal to the moment of the force about the point to which it is translated.*

Fig. 51.

Consider a force F applied to a rigid body at a point A (Fig. 51a). The action of the force will not change if two balanced forces $F' = F$ and $F'' = -F$ are applied at any point B of the body. The resulting three-force system consists of a force F' , equal to F and applied at B , and a couple (F, F'') of moment

$$m = m_B(F). \quad (27)$$

This equation follows from Eq. (23). The theorem is thus proved. The result can also be denoted as in Fig. 51b, with force F

neglected. Here now are two examples on the application of this theorem.

Example 1. In order to maintain the homogeneous bar AB of weight P and length $2a$ in Fig. 52a in equilibrium it is obviously necessary to apply to its middle C a force Q directed vertically up and equal to P in magnitude. According to the theorem just proved, force Q can be replaced by a force Q' applied at end A of the bar and a couple of moment $m = Qa$. If the moment arm of this couple is reduced to h , the forces Q and Q'' have to be increased so that $Fh = Qa$. Consequently, to hold the bar at end A we have to add a couple (F, F') to force Q' . This result, which follows from the theorem, is immediately "felt" when you shift your grip from the middle of the bar (Fig. 52a) to the end (Fig. 52b).

Fig. 52.

Fig. 53.

Example 2. Forces F and $F' = -F$ are applied to the ends of two threads wrapped in opposite direction around drum a) of radius r (Fig. 53); a force $2F$ is applied to the end of a single thread wrapped on drum b) of same radius r . Let us analyse the difference between the actions of these forces.

Acting on drum a) is only the couple (F, F') of moment $2Fr$ which revolves the drum. The force acting on drum b) can be replaced by a force-couple system consisting of a force $2F'' = 2F$ applied at the axle of the drum and a couple $(2F, 2F')$. Thus we find that acting on drum b) are: 1) a couple of same moment as the couple acting on drum a), namely $2Fr$, which rotates the drum, and 2) a force $2F''$ exerting pressure on the drum axle. In other words, both drums revolve similarly, but the axle of drum b) carries a load $2F$, which drum a) does not.

22. Reduction of a Coplanar Force System to a Given Centre.

Let a set of coplanar forces F_1, F_2, \dots, F_n be acting on a rigid body and let O be any point coplanar with them which we shall call the *centre of reduction*. By the theorem proved in § 21, we can transfer all the forces to O as in Fig. 54a. As a result we have acting on the body a system of forces

$$F'_1 = F_1, \quad F'_2 = F_2, \quad \dots, \quad F'_n = F_n \quad (28)$$

applied at O and a system of couples of moments (by Eq. 27):

$$m_1 = m_O(F_1), \quad m_2 = m_O(F_2), \quad \dots, \quad m_n = m_O(F_n). \quad (28')$$

The forces applied at O can be replaced with their resultant $R = \sum F_k$ acting at the same point, or, by Eqs. (28),

$$R = \sum F_k. \quad (29)$$

Similarly, by the theorem of the composition of couples, we can replace all the couples with a coplanar resultant couple of moment $M_O = \sum m_k$; or, by Eqs. (28'),

$$M_O = \sum m_O(F_k). \quad (30)$$

The quantity R , which is the geometric sum of all the forces of the given system, it will be recalled, is called the *principal*

Fig. 54.

vector of the system; we shall call the quantity M_O , which is the sum of the moments of all the forces of the system about O , the *principal moment of the system about O* . Thus we have proved the following theorem: *Any system of coplanar forces acting on a rigid body can be reduced to an arbitrary centre O in such a way that it is replaced by a single force R equal to the principal vector of the system and applied at the centre of reduction O and a single couple of moment M_O equal to the principal moment of the system about O (Fig. 54c).*

It should be noted that R is not the resultant of the force system, as it replaces the system only together with a couple.

It is apparent from the theorem that two force systems with equal principal vectors and principal moments are statically equivalent. Hence, in order to define a coplanar force system it is sufficient to define its principal vector R and principal moment M_O about a centre O .

The magnitude of R can be determined either graphically by constructing a force polygon (see Fig. 54b) or analytically by

Eqs. (10) in § 10; obviously, the magnitude of R does not depend on the location of O . The magnitude of M_O is determined by Eq. (30). In the general case the value of M_O may change if the position of O changes due to the change in the moments of the component forces. Therefore, in defining the principal moment it is necessary to state the point with reference to which it is taken.

Problem 18. External forces F_1 , F_2 , F_3 , and F_4 act on a beam embedded in a wall as shown in Fig. 55a. Determine the internal forces at section ab *.

Solution. Transfer forces F_1 , F_2 , and F_3 acting on the right-hand portion of the beam to the centre O of section ab . By the proved theorem, these forces

Fig. 55.

can be replaced with a single force $R = F_1 + F_2 + F_3$ applied at O and a couple of moment $M_O = m_O(F_1) + m_O(F_2) + m_O(F_3)$. It will be readily realised that if we neglect the shaded portion of the beam, which is subjected to no forces, the mutual interaction of the two loaded parts of the beam will not change. But now, after the three forces have been transferred to O , the whole right-hand portion has no load and can be neglected and the beam drawn as in Fig. 55b. By resolving force R into rectangular components P and Q along the axis of the beam and perpendicular to it, we find that acting

on the left-hand portion along section ab are: 1) a *transverse force* Q which tends to shear the beam along ab ; 2) a *longitudinal force* P causing tension (or, conversely, thrust) in the beam along its axis; 3) a couple of moment M_O , called the *bending moment*, which in the present case causes tension in the upper half of the beam and compression in the lower half. By virtue of the 4th principle, the left-hand portion of the beam acts on the right-hand portion with a force and a couple of the same magnitudes but opposite sense.

The stresses in any other section of the beam can be determined similarly.

Note. The required forces could be found by transferring to O the external forces acting on the left-hand portion of the beam and determining its action along ab on the right-hand portion. But in this case the external forces would include the reactions of the wall, which would have to be determined by examining the equilibrium of the beam as a whole (§ 26). The same would have had to be done in our case if there were any constraints applied to the right-hand portion of the beam.

23. Reduction of a Coplanar Force System to the Simplest Possible Form. The theorem proved in § 22 makes it possible to solve the problem of reducing a given coplanar force system to the simplest possible form. The result will depend on the values of the principal vector R and the principal moment M_O of the system:

* The internal forces at section ab are those with which the parts of the beam on both sides of the section act on each other. By virtue of the theorem proved, the system of these internal forces can be replaced by a single force applied, say, at the centre of the section, and a couple.

1) If $R=0$ and $M_O=0$, the system is in equilibrium. This case of equilibrium will be further examined in the following section.

2) If $R=0$ and $M_O \neq 0$, the system can be reduced to a couple of moment $M_O = \sum m_O(F_k)$. In this case the magnitude of M_O does not depend on the location of the centre O , otherwise we would find that the same system could be replaced by non-equivalent couples, which is impossible.

3) If $R \neq 0$, the system can be reduced to a resultant force. Two cases are possible:

a) $R \neq 0$, $M_O = 0$. In this case the system can immediately be replaced by a single force, i.e., the resultant R going through O ;

b) $R \neq 0$, $M_O \neq 0$. In this case (Fig. 56a) force R can be transferred to a point C about which its moment will be equal to $(-M_O)$. As a result of this operation a couple of moment $(-M_O)$ will be added which will balance the couple of moment M_O , and the whole system will be replaced by a resultant $R' = R$ going through C . The location of C , i.e., the perpendicular distance $d = OC$ ($OC \perp R$) is determined by the equation:

$$Rd = |M_O|. \quad (31)$$

This result can be formulated as follows: If in reducing a force system to a centre O it can be replaced by a force and a couple of moment M_O , it can also be replaced by a resultant $R' = R$ located at such a distance from O that $m_O(R') = M_O$. The method of computation is given in Problem 20.

The same result can also be obtained by drawing a couple of moment M_O as shown in Fig. 56b, with the forces R' and R'' of the couple equal in magnitude to R . The distance $d = OC$ between the two forces can be found by Eq. (31). Cancelling forces R and R'' as balanced, we obtain a resultant $R' = R$ through point C which replaces the system, i.e., the result is the same.

These cases show that if a coplanar force system is not in equilibrium it can be reduced either to a resultant (when $R \neq 0$) or to a couple (when $R = 0$).

Problem 19. Reduce to the simplest possible form the sets of applied forces acting on the beam and truss in Figs 57a and 57b if all the forces are equal in magnitude. Determine the loads on the supports.

Solution. 1) The force polygon P_1, P_2, P_3 is closed, consequently $R = 0$. The sum of the moments of all the forces about any point (for instance point C) is $-Pa$, where P is the magnitude of each force. Hence, the given force system

Fig. 56.

can be reduced to a couple of moment $m = -Pa$. Placing this couple as shown in the diagram by the dashed vectors we conclude that the forces P_1 , P_2 , and P_3 act on the supports with forces Q_1 and Q_2 of magnitude $\frac{Pa}{b}$.

2) Noting that forces F_2 and F_3 (Fig. 57b) form a couple, transfer them as shown in the diagram by the dashed vectors. Forces F_1 and F_3' balance, and the whole system is reduced to a resultant $R = F_2'$.

We see that the action of forces F_1 , F_2 , F_3 is reduced to a vertical load acting on support A. Support B is under no load.

Fig. 57.

Problem 20. Determine the resultant of the forces acting on the beam in Fig. 58 if $P = 3t$, $Q_1 = Q_2 = Q = 4t$, and $CB = a = 0.8$ m.

Solution. Constructing a force polygon with forces P , Q_1 , and Q_2 , we find that the magnitude of force R (the principal vector of the system) is 5 t, for, in the polygon, $be = 2Q \cos 60^\circ = 4$ t, and $ab = 3$ t. Now, taking point C

Fig. 58.

where forces P and Q_2 intersect as the centre of the moments, compute the principal moment of the system: $M_C = m_C(Q_1) = -aQ \cos 30^\circ = -1.6\sqrt{3}$ kg-m, and from Eq. (31) we obtain:

$$d = \frac{|M_C|}{R} = 0.32\sqrt{3} \approx 0.55 \text{ m.}$$

By drawing from C a perpendicular to the direction of R and laying off a segment d on it, we obtain the line of action of the resultant. As $M_C < 0$, the resultant lies to the right of C (the moment of R about C is negative).

24. Conditions for the Equilibrium of a Coplanar Force System. For any given coplanar force system to be in equilibrium it is necessary and sufficient for the following two conditions to be satisfied simultaneously:

$$R=0, \quad M_O=0, \quad (32)$$

where O is any point in a given plane, as at $R=0$ the magnitude of M_O does not depend on the location of O (see § 23, section 2).

The conditions (32) are necessary, for if one of them is not satisfied the force system acting on a body is reduced either to a resultant (when $R \neq 0$) or to a couple (when $M_O \neq 0$) and consequently is not balanced. At the same time, conditions (32) are sufficient, for at $R=0$ the system can be reduced only to a couple of moment M_O , but $M_O=0$, hence the system is in equilibrium.

Let us determine from Eqs. (32) the analytical conditions of equilibrium. They can be expressed in three different forms, as follows.

1. **The Basic Equations of Equilibrium.** The magnitudes of R and M_O are determined by the equations

$$R = \sqrt{R_x^2 + R_y^2},$$

where $R_x = \sum F_{kx}$ and $R_y = \sum F_{ky}$, and $M_O = \sum m_O(F_k)$.

But R can be zero only if both $R_x=0$ and $R_y=0$. Hence, Eqs. (32) will be satisfied if

$$\sum F_{kx} = 0, \quad \sum F_{ky} = 0, \quad \sum m_O(F_k) = 0. \quad (33)$$

Eqs. (33) express the following analytical conditions of equilibrium: *The necessary and sufficient conditions for the equilibrium of any coplanar force system are that the sums of the projections of all the forces on each of two coordinate axes and the sum of the moments of all the forces about any point in the plane must separately vanish.* Eqs. (33) also express the necessary conditions for the equilibrium of a free rigid body subjected to the action of a coplanar set of forces. In the mechanical sense the first two of the equations express the necessary conditions for a body to have no translation parallel to the coordinate axes, and the third equation expresses the condition for it to have no rotation in the plane Oxy .

2. **The Second Form of the Equations of Equilibrium:** *The necessary and sufficient conditions for the equilibrium*

of any coplanar force system are that the sums of the moments of all the forces about any two points A and B and the sum of the projections of all the forces on any axis Ox not perpendicular to AB must separately vanish:

$$\sum m_A(\mathbf{F}_k) = 0, \quad \sum m_B(\mathbf{F}_k) = 0, \quad \sum F_{kx} = 0. \quad (34)$$

The necessity of these conditions is obvious, for if any one of them is not satisfied, then either $\mathbf{R} \neq 0$ or $M_A \neq 0$ ($M_B \neq 0$), and the forces will not be in equilibrium. Let us now prove that these conditions are sufficient. If for a given force system only the first two of Eqs. (34) are satisfied, then $M_A = 0$ and $M_B = 0$. By § 23, such a force system may not be in equilibrium as it may have a resultant \mathbf{R} passing through the points A and B^* (Fig. 59). But from the third equation we must have $R_x = \sum F_{kx} = 0$. As Ox is not perpendicular to AB , the latter condition can be satisfied only if the resultant \mathbf{R} is zero, i.e., if the system is in equilibrium.

Fig. 59.

3. The Third Form of the Equations of Equilibrium (the Equations of Three Moments): The necessary and sufficient conditions for the equilibrium of any coplanar force system are that the sums of the moments of all the forces about any three non-collinear points A , B , C must separately vanish:

$$\sum m_A(\mathbf{F}_k) = 0, \quad \sum m_B(\mathbf{F}_k) = 0, \quad \sum m_C(\mathbf{F}_k) = 0 \quad (35)$$

The necessity of these conditions, as in the previous form, is obvious. Their sufficiency follows from the consideration that if, with all the three equations satisfied, the system would not be in equilibrium it could be reduced to a single resultant passing through points A , B , and C , which is impossible as they are not collinear. Hence, if Eqs. (35) are satisfied a system is in equilibrium.

In all the cases considered we have three conditions for the equilibrium of a coplanar force system. The Eqs. (33) are defined as the basic equations of equilibrium because they impose no restrictions on the choice of the coordinate axes or the centres of moments.

If acting on a body besides a coplanar force system $\mathbf{F}_1, \mathbf{F}_2, \dots, \mathbf{F}_n$ is a system of couples of moments m_1, m_2, \dots, m_s in the same plane, the couples do not enter the equilibrium equations of the force components, as the sum of the components of the forces of a couple parallel to any axis is obviously zero.

* This follows from paragraph 3, a), in § 23.

In the equations of moments, though, the moments of these couples should be added algebraically to the moments of the forces, as the sum of the moments of the two forces of a couple about any centre equals the moment of that couple (see Eq. (24), § 18). Thus, for example, the conditions of equilibrium (33) for a set of forces and couples acting on a body takes the form

$$\sum F_{kx} = 0, \quad \sum F_{ky} = 0, \quad \sum m_O(F_k) + \sum m_i = 0 \quad (36)$$

Eqs. (34) and (35) will change similarly.

25. Equilibrium of a Coplanar System of Parallel Forces. If all the forces acting on a body are parallel, we can take the x axis of a coordinate system perpendicular to them and the y axis parallel to them (Fig. 60). Then the x projections of all the forces will be zero, and the first one of Eqs. (33) becomes an identity $0 = 0$. Hence, for parallel forces we have two equations of equilibrium:

$$\sum F_{ky} = 0, \quad \sum m_O(F_k) = 0, \quad (37)$$

where the y axis is parallel to the forces.

Another form of the conditions for the equilibrium of parallel forces derived from Eqs. (34) is:

$$\sum m_A(F_k) = 0, \quad \sum m_B(F_k) = 0, \quad (38)$$

where the line AB is not parallel to the given forces.

Fig. 60.

26. Solution of Problems. All the general rules of problem solution outlined in § 13 should be followed in solving the problems of this part of the course.

Attention is again drawn to the importance, in proceeding with the solution of a problem, of clearly visualising the specific body whose equilibrium is being considered. The next step is to isolate it and consider it as a free body, drawing all the given forces and the reactions of the constraints acting on it.

Then write the equilibrium equations, choosing those which lead to the simplest system (in which each equation has only one unknown quantity).

The simplest possible equations can be obtained by the following procedure (provided, of course, that the actual computations do not become more involved): a) for the equations of the force projections, take one of the coordinate axes perpendicular to one of the unknown forces; b) for the moment equations, take the moments with respect to the point where the greatest number of unknown forces intersect.

In computing moments it may prove useful to resolve a force into two components and apply Varignon's theorem.

Many problems in statics are solved to determine the reactions of the supports and connections of beams, trusses, etc. In addition to the constraints described in § 4, the following three types are widely used in engineering:

Fig. 61.

1. Pin and Roller Support (Fig. 61, support A). The reaction N_A of this constraint is normal to the surface supporting the rollers.

2. Fixed Pin (Fig. 61, support B). The reaction R_B of such a constraint is through the pin axis and can have any direction in the plane of the diagram. In

solving problems we shall denote reaction R_B by its x and y components, as by finding X_B and Y_B we shall have defined the reaction R_B whose magnitude is $R_B = \sqrt{X_B^2 + Y_B^2}$.

Constraints of the type in Fig. 61 are employed to avoid additional stresses in beam AB due to temperature changes and bending.

3. Fixed Support (Rigid Clamp or Embedding) (Fig. 62). In this case the action of the constraining surfaces on the embedded portion of the beam is that of a system of distributed forces of reaction. By reducing the forces of reaction to a common centre A we can replace them with an immediately unknown force R_A attached at A and a couple M_A of immediately unknown moment. Force R_A can in turn be denoted by its rectangular components X_A and Y_A . Thus, to determine the reactions of a fixed support we must find three unknown quantities X_A , Y_A , and M_A .

Fig. 62.

The direction of reactions in other types of constraints was examined in § 4.

Problem 21. The travelling crane in Fig. 63 weighs $P = 4$ t, its centre of gravity lies on DE , it lifts a load of weight $Q = 1$ t, the length of the jib (the distance of the load from DE) is $b = 3.5$ m, and the distance between the wheels is $AB = 2a = 2.5$ m. Determine the force with which the wheels A and B act on the rails.

Solution. Consider the equilibrium of the crane-and-load system taken as a free body: the active forces are P and Q , the unknown forces are the reactions N_A and N_B of the removed constraints. Taking A as the centre of

the moments of all the forces and projecting the parallel forces on a vertical axis, we obtain, by the equilibrium equations (37):

$$\begin{aligned} -Pa + N_B \cdot 2a - Q(a + b) &= 0, \\ N_A + N_B - P - Q &= 0, \end{aligned}$$

solving which we find:

$$N_A = \frac{P}{2} - \frac{Q}{2} \left(\frac{b}{a} - 1 \right) = 1.1 \text{ t};$$

$$N_B = \frac{P}{2} + \frac{Q}{2} \left(\frac{b}{a} + 1 \right) = 3.9 \text{ t}.$$

To verify the solution, write the equation of the moments about B :

$$-N_A 2a + Pa - Q(b - a) = 0.$$

Fig. 63.

Fig. 64.

Substituting the value of N_A , we find that the equation is satisfied. The pressures exerted by the wheels on the rails are respectively equal to N_A and N_B in magnitude and directed vertically down.

From the solution we see that at

$$Q = \frac{a}{b-a} P = 2.22 \text{ t}$$

the reaction N_A is zero and the left wheel no longer presses on the rail. If the load Q is further increased the crane will topple over. The maximum load Q at which equilibrium is maintained is determined by the equation $\sum m_B(F_k) = 0$.

Problem 22. One end of a uniform beam AB weighing P kg (Fig. 64) rests at A against a corner formed by a smooth horizontal surface and block D , and at B on a smooth plane inclined α degrees to the horizontal. The beam's inclination to the horizontal is equal to β . Determine the pressure of the beam on its three constraints.

Solution. Consider the equilibrium of the beam as a free body. Acting on it are the given force P applied at the middle of the beam and the reactions R , N_1 , and N_2 of the constraints directed normal to the respective surfaces. Draw the coordinate axes as in Fig. 64 and write the equilibrium equations (33), taking the moments about A , where two of the unknown forces intersect. First compute the projections of all the forces on the coordinate axes and their moments about A and tabulate the results*. The symbols in the table are $AB = 2a$ and $\angle KAB = \gamma$ (AK is the moment arm of force R about point A).

* On tabulating data for problem solutions see footnote on p. 38.

F_k	N_1	N_2	P	R
F_{kx}	0	N_2	0	$-R \sin \alpha$
F_{ky}	N_1	0	$-P$	$R \cos \alpha$
$m_A(F_k)$	0	0	$-Pa \cos \beta$	$R2a \cos \gamma$

Now write the equilibrium equations:

$$\begin{aligned} N_2 - R \sin \alpha &= 0, \\ N_1 - P + R \cos \alpha &= 0, \\ -Pa \cos \beta + 2Ra \cos \gamma &= 0. \end{aligned}$$

From the last equation we find:

$$R = \frac{P \cos \beta}{2 \cos \gamma}.$$

As AK is parallel to the inclined plane, $\angle KAx = \alpha$, whence $\gamma = \alpha - \beta$ and finally

$$R = \frac{P \cos \beta}{2 \cos (\alpha - \beta)}.$$

Solving the first two equations, we obtain:

$$N_1 = P \left[1 - \frac{\cos \alpha \cos \beta}{2 \cos (\alpha - \beta)} \right], \quad N_2 = P \frac{\sin \alpha \cos \beta}{2 \cos (\alpha - \beta)}.$$

The forces exerted on the surfaces are equal in magnitude to the respective reactions and opposite in sense.

The values of N_1 and N_2 can be verified by solving the equations of moments about the points of intersection of R and N_2 and R and N_1 .

From this solution we can draw the following conclusion: If, in order to determine the projections or moments of any force or forces, we need to know a quantity (e.g., the length of a line or size of an angle) not given in the statement of the problem, we should denote that quantity by a symbol and include it in the equilibrium equations. If the introduced quantity is not cancelled out in the course of the computations, it should be expressed in terms of given quantities.

Problem 23. Acting on a symmetrical arch of weight $P = 8$ t (Fig. 65) is a set of forces reduced to a force $Q = 4$ t applied at D and

Fig. 65.

a couple of moment $M_D = 12$ t-m. The dimensions of the arch are $a = 10$ m, $b = 2$ m, $h = 3$ m, and $\alpha = 60^\circ$. Determine the reactions of the pin B and the roller A .

Solution. Consider the equilibrium of the arch as a free body. Acting on it are the given forces P and Q and a couple of moment M_D , and also the reactions of the supports N_A , X_B , Y_B (the reaction of the pin being denoted by its rectangular components as in Fig. 61). In this problem it is more convenient to use Eqs. (34), taking the moments about A and B and the force projections on axis Ax , and each equation will contain one unknown force. Compute the moments and the force projections and tabulate the information as shown. In computing the moments of force Q , resolve it into rectangular components Q_x and Q_y and apply Varignon's theorem.

F_k	N_A	P	X_B	Y_B	Q	M_D
F_{kx}	0	0	X_B	0	$Q \cos \alpha$	0
$m_A(F_k)$	0	$-P \frac{a}{2}$	0	$Y_B a$	$- Q_x h - Q_y b$	M_D
$m_B(F_k)$	$-N_A a$	$P \frac{a}{2}$	0	0	$- Q_x h + Q_y (a - b)$	M_D

Writing the equilibrium equations and taking into account that $|Q_x| = Q \cos \alpha$, and $|Q_y| = Q \sin \alpha$, we obtain:

$$X_B + Q \cos \alpha = 0, \quad (a)$$

$$Y_B a - P \frac{a}{2} - h Q \cos \alpha - b Q \sin \alpha + M_D = 0, \quad (b)$$

$$-N_A a + P \frac{a}{2} - h Q \cos \alpha + (a - b) Q \sin \alpha + M_D = 0. \quad (c)$$

Solving the equations, we find

$$X_B = -Q \cos \alpha = -2 \text{ t},$$

$$Y_B = \frac{P}{2} + Q \frac{b \sin \alpha + h \cos \alpha}{a} - \frac{M_D}{a} \approx 4.09 \text{ t},$$

$$N_A = \frac{P}{2} + Q \frac{(a - b) \sin \alpha - h \cos \alpha}{a} + \frac{M_D}{a} \approx 7.37 \text{ t}.$$

The value of X_B is negative, which means that the sense of the x component of the reaction at B is opposite to that shown in the diagram, which could have been foreseen. The total reaction at B can be found from the geometrical sum of the rectangular components X_B and Y_B , its magnitude being

$$R_B = \sqrt{X_B^2 + Y_B^2} \approx 4.55 \text{ t}.$$

If the sense of the couple acting on the arch were opposite to that indicated in Fig. 65, we would have $M_D = -12 \text{ t-m}$. In this case $Y_B = 6.49 \text{ t}$, $N_A = 4.97 \text{ t}$, while X_B would remain the same.

To check the solution, write the equation for the projections on axis Ay :

$$N_A + Y_B - P - Q \sin \alpha = 0. \quad (d)$$

Substituting the obtained values of N_A and Y_B , we find that they satisfy the equation (substitution should be carried out in both the general form, to verify the equations, and in the numerical solution to verify the computations).

It should be borne in mind that this method of verification may not reveal errors due to mistakes in computing the projections or the moments of the forces perpendicular to Ay . Therefore, that portion of the computations has to be further verified or an additional equation of moments about, say, D can be written.

Note also the following. In writing Eqs. (34) the projection axis should not be taken perpendicular to AB , or in our case not along Ay . If, nevertheless, we were to write a third equation of projections on Ay , we would have obtained a system of equations (b), (c), (d) with only two unknown quantities N_A and Y_B (one of the equations would be a corollary of the other two) and we would be unable to determine the reaction X_B .

Problem 24. The beam in Fig. 66a is embedded in a wall at an angle $\alpha = 60^\circ$ to it. The length of the portion AB is $b = 0.8$ m and its weight is $P = 100$ kg. The beam supports a cylinder of weight $Q = 180$ kg. The distance AE along the beam from the wall to the point of contact with the cylinder is $a = 0.3$ m. Determine the reactions of the embedding.

Solution. Consider the equilibrium of the beam as a free body. Acting on it are force P applied halfway between

A and B , force F applied perpendicular to the beam at E (but not force Q , which is applied to the cylinder, not to the beam!), and the reactions of the embedding, indicated by the rectangular components X_A and Y_A and a couple of moment M_A (see Fig. 62).

In order to write the equations of equilibrium (33) let us compute the projections of all the forces on each of the coordinate axes and their moments about A :

F_k	X_A	Y_A	F	P	M_A
F_{kx}	X_A	0	$F \cos \alpha$	0	0
F_{ky}	0	Y_A	$-F \sin \alpha$	$-P$	0
$m_A(F_k)$	0	0	$-Fa$	$-P \frac{b}{2} \sin \alpha$	M_A

To determine F we resolve force Q , which is applied at the centre of the cylinder, into components F and N respectively perpendicular to the beam and the wall (Fig. 66b). From the parallelogram we obtain:

$$F = \frac{Q}{\sin \alpha}.$$

Writing the equations of equilibrium and substituting the value of F , we have:

$$X_A + Q \cot \alpha = 0, \quad Y_A - Q - P = 0, \quad M_A - Q \frac{a}{\sin \alpha} - P \frac{b}{2} \sin \alpha = 0.$$

Fig. 66.

Solving these equations we find:

$$X_A = -Q \cot \alpha = -103.8 \text{ kg.}$$

$$Y_A = P + Q = 280 \text{ kg.}$$

$$M_A = Q \frac{a}{\sin \alpha} + P \frac{b}{2} \sin \alpha = 96.9 \text{ kg}\cdot\text{m.}$$

The reaction of the wall consists of force $R_A = \sqrt{X_A^2 + Y_A^2}$ and a couple of moment M_A .

The solution of this problem once again underlines the fundamental point: the equilibrium equations include only the forces *acting directly* on the body whose equilibrium is being considered.

Problem 25. A string supporting a weight $Q = 240 \text{ kg}$ passes over two pulleys C and D as shown in Fig. 67. The other end of the string is secured at B , and the frame is kept in equilibrium by a guy wire EE_1 . Neglecting the weight of the frame and the friction in the pulleys, determine the tension in the guy wire and the reactions at A , if the constraint at A is a smooth pivot allowing the frame to turn about its axis. The dimensions are as shown in the diagram.

Solution. Consider the whole system of the frame and the portion $KDCM$ of the string as a single free rigid body (see Problem 10). Acting on it are the following external forces: the weight Q of the load, the tension F in section DB of the string, and the reactions T , X_A , and Y_A of the constraints. The internal forces cancel each other and are not shown in the diagram. As the friction of the pulleys is neglected, the tension in the cable is uniform throughout its whole length and $F = Q$.

Introducing angles α and β , let us compute the projections of all the forces on the coordinate axes and their moments about A .

Fig. 67.

F_k	Q	F	T	X_A	Y_A
F_{kx}	0	$F \cos \alpha$	$-T \cos \beta$	X_A	0
F_{ky}	$-Q$	$-F \sin \alpha$	$-T \sin \beta$	0	Y_A
$m_A(F_k)$	$-Q \cdot 1.0$	$-F \cdot 0.9 \sin \alpha$	$T \cdot 1.2 \sin \beta$	0	0

From the right-angle triangles AEE_1 and ADB we find that $EE_1 = 2.0$ m and $DB = 1.5$ m, whence $\sin \alpha = \sin \beta = 0.8$, $\cos \alpha = \cos \beta = 0.6$, and $\alpha = \beta$. Substituting for the trigonometric functions their values and assuming $F = Q$, the equations of equilibrium give:

$$\begin{aligned} 0.6Q - 0.6T + X_A &= 0, \\ -Q - 0.8Q - 0.8T + Y_A &= 0, \\ -1.0Q - 0.72Q + 0.96T &= 0, \end{aligned}$$

solving which, we find:

$$T = \frac{43}{24} Q = 430 \text{ kg}, \quad X_A = \frac{19}{40} Q = 114 \text{ kg}, \quad Y_A = \frac{97}{30} Q = 776 \text{ kg}.$$

Attention is drawn to the following conclusions: 1) in writing equations of equilibrium, any system of bodies which remains fixed when the constraints are removed can be regarded as a rigid body; 2) the internal forces acting on the parts of a system (in this case the tension of the string DC acting on pulleys C and D) are not included in the equilibrium equations as they cancel each other.

27. Equilibrium of Systems of Bodies. In many cases the static solution of engineering structures is reduced to an investigation of the conditions for the equilibrium of systems of connected bodies. We shall call the constraints connecting the parts of a given structure *internal*, as opposed to *external* constraints which connect a given structure with other bodies (e.g., the supports of a bridge).

If a structure remains rigid after the external constraints (supports) are removed, the problems of statics are solved for it as for a rigid body. Such examples were considered in Problems 23 and 25 (see Figs 65 and 67).

Fig. 68.

However, an engineering structure may not necessarily remain rigid when the external constraints are removed. An example of such a structure is the three-pin arch in Fig. 68. If supports A and B are removed the arch is no longer rigid, for its parts can turn about pin C .

According to the principle of solidification, for a system of forces acting on such a structure to be in equilibrium it must satisfy the conditions of equilibrium for a rigid body. It was pointed out, though, that these conditions, while necessary, were not sufficient, and therefore not all the unknown quantities could be determined from them. In order to solve such a problem it is necessary to examine additionally the equilibrium of one or several parts of the given structure.

For example, for the forces acting on the three-pin arch in Fig. 68 we have three equations with four unknown quantities, X_A , Y_A , X_B , Y_B . By investigating the conditions for the equilib-

rium of the left- or right-hand members of the arch we obtain three more equations with two more unknown quantities, X_C and Y_C (not shown in Fig. 68). Solving the system of six equations we can determine all six unknown quantities.

Another method of solving such problems is to divide a structure into separate bodies and write the equilibrium equations for each as for a free body. The reactions of the internal constraints will constitute pairs of forces equal in magnitude and opposite in sense. For a structure of n bodies, each of which is subjected to the action of a coplanar force system, we thus have $3n$ equations from which we may determine $3n$ unknown quantities (in other force systems the number of equations is, of course, different). If the number of unknown quantities is greater than the number of equations, the problem is statically indeterminate. An example of this method of solution is given in Problem 27.

Fig. 69.

Problem 26. The horizontal member AD of the bracket in Fig. 69 weighs $P_1 = 15$ kg, and the inclined member CB weighs $P_2 = 12$ kg. Suspended from the horizontal member at D is a load of weight $Q = 30$ kg. Both members are attached to the wall and to each other by smooth pins (the dimensions are shown in the diagram). Determine the reactions at A and C .

Solution. Considering the bracket as a whole as a free body, we find that acting on it are the given forces P_1 , P_2 , Q and the reactions of the supports X_A , Y_A , X_C , Y_C . But with its constraints removed the bracket is no longer a rigid body, because the members can turn about pin B . On the other hand, by the principle of solidification, if it is in equilibrium the forces acting on it must satisfy the conditions of static equilibrium. We may therefore write the corresponding equations:

$$\begin{aligned}\sum F_{kx} &= X_A + X_C = 0, \\ \sum F_{ky} &= Y_A + Y_C - P_1 - P_2 - Q = 0, \\ \sum m_A(F_k) &= X_C 4a - Y_C a - P_2 a - P_1 \cdot 2a - Q \cdot 4a = 0.\end{aligned}$$

We find that the three equations contain four unknown quantities X_A , Y_A , X_C , Y_C . Let us therefore investigate additionally the equilibrium conditions of member AD (Fig. 69b). Acting on it are forces P_1 and Q and the reactions X_A , Y_A , X_B , and Y_B . If we write the required fourth equation for the moments of these forces about B we shall avoid introducing two more unknown quantities, X_B and Y_B . We have:

$$\sum m_B(F_k) = -Y_A \cdot 3a + P_1 a - Qa = 0.$$

Solving the system of four equations (starting with the last one) we find:

$$Y_A = \frac{1}{3}(P_1 - Q) = -5 \text{ kg}, \quad Y_C = \frac{2}{3}P_1 + P_2 + \frac{4}{3}Q = 62 \text{ kg},$$

$$X_C = \frac{2}{3}P_1 + \frac{1}{2}P_2 + \frac{4}{3}Q = 56 \text{ kg}, \quad X_A = -X_C = -56 \text{ kg}.$$

We see that the sense of forces Y_A and X_A is opposite to that shown in the diagram. The reactions at B can be determined from equations for the x and y projections of the forces acting on AD ; they are: $X_B = -X_A$, $Y_B = P_1 + Q - Y_A = 50 \text{ kg}$.

It should be noted that in solving a system of simultaneous equations the values in every successive equation should be substituted with the sign obtained in the preceding equation. In the present case, for example, the value substituted for Y_A in the last equation is -5 kg , not 5 kg . This also suggests that it would be wrong, on finding that $Y_A = -5 \text{ kg}$, to alter the sense of Y_A in the diagram and consider $Y_A = 5 \text{ kg}$, for this could lead to wrong solutions of subsequent equilibrium equations.

We see that in solving problems of statics there is no need to investigate *all* the conditions for the equilibrium of a given body. If a problem does not require the determination of the reactions of a constraint, the equations should, if possible, not include those unknown reactions. That is just what we did in the above problem in examining the equilibrium of AD when we wrote only one equation of the moments about B .

Problem 27. The horizontal beam AB in Fig. 70a of weight $Q = 20 \text{ kg}$ is attached to the wall by a smooth pin at A and rests on a support at C . Beam BE of weight $P = 40 \text{ kg}$ is hinged to AB and rests against D as shown. Determine the reactions of the supports if $CB = \frac{1}{3}AB$, $DE = \frac{1}{3}BE$, $\alpha = 45^\circ$.

Solution. Let us consider the members of the system separately and investigate the equilibrium of BE and AB . Acting on BE , which we regard as a free body (Fig. 70a), are force P and the reactions of the supports N_D , X_B , Y_B . Assuming $BE = a$, we write the equations (33):

$$\begin{aligned} \sum F_{kx} &\equiv X_B - N_D \sin \alpha = 0, \\ \sum F_{ky} &\equiv Y_B - P + N_D \cos \alpha = 0, \\ \sum m_B (F_k) &\equiv N_D \frac{2}{3}a - P \frac{a}{2} \cos \alpha = 0, \end{aligned}$$

solving which we obtain:

$$N_D = \frac{3}{4}P \cos \alpha = 21.2 \text{ kg}, \quad X_B = \frac{3}{8}P \sin 2\alpha = 15 \text{ kg},$$

$$Y_B = P \left(1 - \frac{3}{4} \cos^2 \alpha \right) = 25 \text{ kg}.$$

Considering beam AB as a free body, we have acting on it force Q , the reactions of the external supports N_C , X_A , Y_A , and the action X'_B and Y'_B of

Fig. 70.

BE transmitted by pin B (Fig. 70b). According to the 4th principle, forces X'_B and Y'_B are respectively equal to X_B and Y_B in magnitude and opposite in sense.

Denoting $AB = b$ and writing the equilibrium equations (34) for the forces acting on the beam, we have:

$$\sum F_{kx} \equiv X_A - X'_B = 0.$$

$$\sum m_A(F_k) \equiv Y'_B b + N_C \cdot \frac{2}{3} b - Q \frac{b}{2} = 0.$$

$$\sum m_C(F_k) \equiv -Y'_A \cdot \frac{2}{3} b + Q \frac{b}{6} - Y'_B \frac{b}{3} = 0.$$

Assuming $X'_B = X_B$ and $Y'_B = Y_B$ and solving for the unknown quantities, we obtain:

$$X_A = X_B = 15 \text{ kg}, \quad Y_A = \frac{1}{4} Q - \frac{1}{2} Y_B = -7.5 \text{ kg},$$

$$N_C = \frac{3}{4} Q + \frac{3}{2} Y_B = 52.5 \text{ kg}.$$

We see that all the reactions except Y_A are directed as in Fig. 70; the true direction of Y_A is vertically downwards. In solving problems by this method it should be remembered that if the action of one body on another is denoted by a force R or its rectangular components X and Y , then according to the 4th principle, the action of the second body on the first must be denoted by a force R' equal to R in magnitude and opposite in sense, or by its rectangular components X' and Y' respectively equal to X and Y in magnitude and opposite in sense.

Beware of the following two mistakes which are often made in solving problems by this method: 1) The student fails to draw forces X' and Y' in the opposite direction of X and Y , which makes for a wrong answer; 2) Having drawn the forces X' and Y' correctly, the student assumes, in solving the equations, that $X' = -X$ and $Y' = -Y$, obtaining a wrong answer; actually the same error is made as in the first case.

To preclude the possibility of such mistakes, it is suggested that, as a rule, the method of solution of Problem 26 be adopted. Furthermore, it usually gives simpler systems of equations, as the internal forces do not enter the equations for the structure as a whole.

Problem 28. A horizontal force F acts on the three-pin arch in Fig. 71. Show that in determining the reactions of supports A and B force F cannot be transferred along its action line to E .

Solution. Isolating the arch from its external supports A and B , we obtain a deformable structure which cannot be treated as rigid. Consequently, the point of action of the force acting on the structure cannot be transferred along DE even to determine the conditions for the equilibrium of the structure (see § 3, corollary of the 1st and 2nd principles).

Fig. 71.

Let us demonstrate this by solving the problem (the weight of the arch is neglected). Consider first the right-hand member of the arch as a free body. Acting on it are only two forces, the reactions R_B and R_C of the pins B and C (force R_C is not shown in the diagram). To be in equilibrium, these two forces must be directed along the same line, i.e., along BC , and consequently the reaction R_B is directed along BC .

Investigating now the equilibrium of the arch as a whole, we find that acting on it are three forces, the given force F and the reactions of the supports R_B (whose direction we have established) and R_A . From the theorem of three forces we know that if the system is in equilibrium the forces must be concurrent. Thus we obtain the direction of R_A . The magnitudes of R_A and R_B can be found by the triangle rule.

If we apply force F at E and, reasoning in the same way, make the necessary constructions (Fig. 71b), we shall find that the reactions of the supports R_A and R_B are different both in magnitude and in direction.

28. Distributed Forces. In engineering problems we often have to deal with loads distributed over an area according to a known mathematical law. Let us examine some simple cases of distributed coplanar forces.

Fig. 72.

Fig. 73.

A plane system of distributed forces is characterised by the load per unit length of the line of application, which is called the *intensity* q . The dimension of intensity is kilogram per metre: kg/m.

1) **Forces Uniformly Distributed Along a Straight Line** (Fig. 72). The intensity q of such a system is a constant quantity. In solving problems of statics such a force system can be replaced by its resultant Q of magnitude

$$Q = aq \quad (39)$$

applied at the middle of AB .

2) **Forces Distributed Along a Straight Line According to a Linear Law** (Fig. 73). An example of such a load is the pressure of water against a dam, which drops from a maximum at the bottom to zero at the surface. For such forces the intensity q varies from zero to q_m . The resultant Q is determined in the same manner as the resultant of the gravity forces acting on a homogeneous triangular lamina ABC . As the

weight of a homogeneous lamina is proportional to its area, the magnitude of Q is

$$Q = \frac{1}{2} a q_m \quad (40)$$

and is applied at a point at a distance of $\frac{a}{3}$ from side BC of triangle ABC (see § 56, Sec. 2).

3) Forces Distributed Along a Straight Line According to an Arbitrary Law (Fig 74). The magnitude of the resultant Q of such forces is, by analogy with the force of gravity, equal to the area of the figure $ABDE$ drawn to scale and passes through the centre of gravity of that area (determination of centre of gravity will be examined in § 54).

Fig. 74.

Fig. 75.

4) Forces Uniformly Distributed Along the Arc of a Circle (Fig. 75). An example of such forces is the hydrostatic pressure on the sides of a cylindrical vessel. It is apparent from the laws of symmetry that the sum of the y projections, which are perpendicular to the axis of symmetry, is zero, and consequently their resultant Q is directed along Ox . In magnitude $Q = Q_x = \sum (q \Delta l_k) \cos \varphi_k$, where $q \Delta l_k$ is the pressure on an arc element of length Δl_k and φ_k is the angle between the force and the x axis. But from the diagram it is apparent that $\Delta l_k \cos \varphi_k = \Delta y_k$. Taking the common multiplier outside of the summation sign, we obtain $Q = \sum q \Delta y_k = q \sum \Delta y_k = q \cdot AB$, whence

$$Q = qh, \quad (41)$$

where h is the length of the chord intersecting arc \widehat{AB} .

Problem 29. An evenly distributed force of intensity q_0 kg/m acts on a cantilever beam whose dimensions are shown in Fig. 76. Neglecting the weight of the beam and assuming the forces acting on the embedded portion to be distributed according to a linear law, determine the magnitude of the maximum intensities q_m and q'_m of the given forces if $b = 2a$ (compare with the diagram for Problem 15, § 17).

Solution. Replace the distributed forces by their resultants Q , R , and R' . By Eqs. (39) and (40),

$$Q = q_0 b, \quad R = \frac{1}{2} q_m a, \quad R' = \frac{1}{2} q'_m a.$$

Now write the equilibrium conditions (37) for the parallel forces acting on the beam:

$$\sum F_{ky} \equiv Q + R - R' = 0, \quad \sum m_C (F_k) \equiv R \frac{a}{3} - Q \left(\frac{b}{2} + \frac{a}{3} \right) = 0.$$

Substituting the values of Q , R , and R' and solving the equations, we obtain:

$$q_m = \left(3 \frac{b^2}{a^2} + 2 \frac{b}{a} \right) q_0; \quad q'_m = \left(3 \frac{b^2}{a^2} + 4 \frac{b}{a} \right) q_0.$$

At $b = 2a$ we have $q_m = 16 q_0$ and $q'_m = 20 q_0$.

Problem 30. A dam of rectangular cross section of height h and width a rests on a horizontal foundation AB (Fig. 77). The weight of a unit volume

Fig. 76.

Fig. 77.

of the impounded water is γ , and the weight of a unit volume of the dam filling is γ_1 . Assuming the forces acting on the foundation to be linearly distributed (according to a trapezoidal law), determine the minimum and maximum intensities (q_1 and q_2) of the forces.

Solution. Consider a section of the dam of unit length perpendicular to the plane of the diagram. Consider further the forces acting on the section as if they were applied at the median cross section shown in Fig. 77. These forces are: the pressure of the water P , the weight of the dam Q , the vertical reaction of the foundation, which we shall denote by two forces R and R' , and the horizontal reaction F .

As the pressure of the water is determined by the weight of a column of height h , the maximum intensity of loading is $q_m = \gamma h$, and by Eq. (40), $P = \frac{1}{2} q_m h = \frac{1}{2} \gamma h^2$. The component R of the reaction of the foundation is the resultant of linearly distributed forces of intensity q_1 ; consequently, by Eq. (39), $R = q_1 a$. Component R' is the resultant of linearly distributed forces with intensity varying from zero to $(q_2 - q_1)$; hence, by Eq. (40),

$R' = (q_2 - q_1) \frac{a}{2}$. Finally, the weight of a unit length of the dam is $Q = \gamma_1 ah$, whence

$$P = \frac{1}{2} \gamma h^2, \quad Q = \gamma_1 ah, \quad R = q_1 a, \quad R' = (q_2 - q_1) \frac{a}{2}.$$

Writing now the equilibrium equations (33) and taking the moments about the point of application of force R , we obtain:

$$\begin{aligned} \sum F_{kx} &= P - F = 0, \\ \sum F_{ky} &= R + R' - Q = 0, \\ \sum m_O(F_k) &= -P \frac{h}{3} + R' \frac{a}{6} = 0. \end{aligned}$$

The first equation gives the horizontal reaction F . From the second and third equations we find:

$$R' = 2P \frac{h}{a}; \quad R + R' = Q.$$

Substituting the values of the forces in the equations we obtain a simultaneous system of two equations:

$$q_2 - q_1 = 2\gamma \frac{h^2}{a^2}, \quad q_2 + q_1 = 2\gamma_1 h,$$

solving which we finally obtain:

$$q_1 = \left(\gamma_1 - \frac{h^2}{a^2} \gamma \right) h, \quad q_2 = \left(\gamma_1 + \frac{h^2}{a^2} \gamma \right) h.$$

It is worth noting that if the ratio of the width of the dam a to its height h is determined by the relation

$$\frac{a}{h} = \sqrt{\frac{\gamma}{\gamma_1}},$$

q_1 becomes zero. If $a < h \sqrt{\frac{\gamma}{\gamma_1}}$, then q_1 is negative, which means that a portion of the dam along A does not press on the foundation, creating the danger of seepage which can lead to the destruction of the dam.

Problem 31. A gas cylinder of height H with an internal diameter d contains gas compressed to p kg/m². The walls of the cylinder are of thickness a . Determine: 1) the longitudinal, and 2) the lateral stresses in the walls (stress is the ratio of the expanding force to the area of the cross section).

Solution. 1) Let us cut the cylinder with a plane perpendicular to its axis and investigate the equilibrium of one portion of the cylinder (Fig. 78a). Acting on it parallel to the cylinder axis are two forces: the pressure on the bottom $F = \frac{\pi d^2}{4} p$ and the resultant Q

Fig. 78.

of the set of distributed forces acting on the cross section (the action of the removed portion). For equilibrium we have $Q = F = \frac{\pi d^2}{4} p$. Assuming the area of the cross section to be approximately πda , we obtain the following expansion stress σ_1 :

$$\sigma_1 = \frac{Q}{\pi da} = \frac{1}{4} \frac{d}{a} p \text{ kg/m}^2.$$

2) Now cut the cylinder with a plane passing through the axis and examine the equilibrium of one half of it, assuming all the forces to be acting on it in the plane of the median section (Fig. 78b). Acting on this half of the cylinder are: a) the pressure of the gas of intensity $q = pH$ distributed uniformly along a semicircle (from Eq. (41) its resultant is $R = qd = pHd$) and b) the forces distributed along sections A and B (the action of the removed half) whose resultants are S_1 and S_2 ; by virtue of symmetry, $S_1 = S_2 = S$. From the conditions of equilibrium we have $S_1 + S_2 = R$, whence $S = \frac{1}{2} pHd$. As the area of the section, along which force S is distributed is aH (neglecting the area of the section of the cylinder bottom), we find the expansion stress

$$\sigma_2 = \frac{S}{aH} = \frac{1}{2} \frac{d}{a} p \text{ kg/m}^2.$$

It will be noticed that the transverse stress is twice as large as the longitudinal stress.

Chapter 5

ELEMENTS OF GRAPHICAL STATICS

29. Force and String Polygons. Reduction of a Coplanar Force System to Two Forces. In engineering problems graphical methods are often used which, though less accurate than analytical methods, produce faster and more easily visualised results.

Fig. 79.

The graphical method of solving problems of statics for coplanar force systems is based on the construction of force and string (or funicular) polygons.

Consider a system of three forces F_1 , F_2 , F_3 acting on a rigid body (Fig. 79a). In Fig. 79b is constructed a force polygon $abcd$

with the given forces as its sides*. It will be recalled that when the end of the last force coincides with the beginning of the first force the polygon is said to be *closed*; otherwise it is said to be *open*.

From an arbitrary point O (the pole) in the plane of the force polygon and not collinear with the sides of the polygon draw to the vertices of the polygon rays Oa , Ob , Oc , Od , which we shall number 01 , 12 , 23 , and 30 (reading them "zero-one", "one-two", etc., as they denote the numbers of the forces coincident at the respective vertices).

Now take in Fig. 79a an arbitrary point A and draw through it a line parallel to ray 01 till its intersection with the action line of force F_1 at point B . From B draw a line parallel to ray 12 till its intersection with the action line of force F_2 at C , etc. The resulting figure $ABCDE$ is called a *string (funicular) polygon*. (If we take a string, pin it down at A and E and apply forces F_1 , F_2 , and F_3 to it at points B , C , and D , then, when equilibrium is maintained, it will take the shape of the broken line $ABCDE$. Hence the name of the polygon.)

A string polygon is *closed* if its first and last strings (AB and DE in our example) coincide, i.e., if they are collinear; otherwise the string polygon is said to be *open*.

By such a construction it is possible to replace any coplanar force system with two forces directed along the first and last strings (AB and DE) of the polygon. We may observe from examining the construction in Fig. 79b that by drawing the rays Oa , Ob , etc., we have resolved each of the given forces F_1 , F_2 , F_3 into two forces, as

$$F_1 = \overline{ab} = \overline{aO} + \overline{Ob}, \quad F_2 = \overline{bc} = \overline{bO} + \overline{Oc}, \quad F_3 = \overline{cd} = \overline{cO} + \overline{Od}.$$

But we know (see § 7, Fig. 17) that forces equal to \overline{aO} and \overline{Ob} can replace F_1 , wherever they are applied along its action line. Let us apply the two forces at point B , which was obtained by the construction of the string polygon (Fig. 79a). Similarly, let us replace forces F_2 and F_3 by forces \overline{bO} and \overline{Oc} , and \overline{cO} and \overline{Od} , applying them at points C and D respectively. Note that forces \overline{Ob} , \overline{bO} and \overline{Oc} , \overline{cO} directed along lines BC and CD cancel out, as (from Fig. 79b) $\overline{Ob} = -\overline{bO}$ and $\overline{Oc} = -\overline{cO}$. Thus the system of forces F_1 , F_2 , and F_3 is replaced by two forces \overline{aO} and \overline{Od} directed along the first and last strings AB and DE of the string polygon.

Analogous results are obtainable for any number of forces.

* We shall denote the forces of a force polygon by numbers, e.g., 1 for F_1 , 2 for F_2 , etc.

30. Graphical Determination of a Resultant. If a force polygon constructed for a given coplanar system is not closed (the principal vector $\mathbf{R} \neq 0$) the system, by § 23, can be reduced to a single resultant.

Graphically the resultant can be determined by successively applying the parallelogram rule. With many forces, however, this becomes too cumbersome. Construction of force and string polygons simplifies the problem.

Fig. 80.

Fig. 81.

Let a set of forces F_1, F_2, F_3, F_4 be acting on a rigid body (Fig. 80a) and let $abcde$ in Fig. 80b be a force polygon drawn to scale. Its closing side ae represents the magnitude and direction of the resultant \mathbf{R} . To determine its point of application, connect the vertices a, b, c, d, e with an arbitrary pole O and construct a string polygon $ABCDEF$, where $Ab \parallel aO, BC \parallel bO$, etc. (Fig. 80a). The given forces, we know, can be replaced by two forces directed along AB and EF . Hence, their resultant (and consequently the resultant of the forces F_1, F_2, F_3, F_4) passes through

the point of intersection of AB and EF . Thus, by constructing a string polygon and continuing the first and last strings till their intersection, we obtain a point K through which the resultant of the force system passes. By drawing through K a line parallel to ae and applying force \mathbf{R} at any point on it we obtain the resultant.

A similar construction for parallel forces is shown in Fig. 81. The force polygon in this case is a line segment and the resultant $\mathbf{R} = ae$.

31. Graphical Determination of a Resultant Couple. If a force polygon constructed for a given coplanar force system closes while the string polygon remains open, the system can be reduced to a resultant couple.

For, if a force polygon $abcde$ constructed with the given forces F_1, F_2, F_3, F_4 is closed (Fig. 82), rays aO and Oe coincide*. Then the first and last strings AB and EF of the string polygon, if it is not closed, are parallel.

It follows from § 29 that the given forces may be replaced by two forces equal, in the present case, to \overline{aO} and \overline{Oa} (as $\overline{Oe} = \overline{Oa}$) and directed along AB and EF . Thus, the force system F_1, F_2, F_3, F_4 is replaced by the couple $(\overline{aO}, \overline{Oa})$ with a moment arm d . The moment of this couple is Oad , where Oa is measured to the scale of the forces in the force polygon and d is measured to the scale of the original diagram.

Fig. 82.

32. Graphical Conditions of Equilibrium of a Coplanar Force System. The results obtained in the foregoing sections show that for any coplanar system of forces acting on a rigid body to be in equilibrium it is necessary and sufficient for the force and string polygons constructed with the given forces to be closed (the graphical conditions of equilibrium).

For, if any of the two polygons is not closed, a system can be reduced either to a resultant force or to a resultant couple, hence it will not be in equilibrium. If, on the other hand, both polygons close the forces acting on the body may, apparently, be reduced to two equal collinear forces of opposite sense (Fig. 82, when $d=0$), and the body is in equilibrium.

33. Determination of the Reactions of Constraints. Let us determine graphically the reactions of the supports A and K of the truss in Fig. 83a. First draw the truss to a suitable scale (e.g., 0.4 m in 1 cm) and denote the given forces F_1, F_2, F_3 acting on it and the reactions of the supports R_4 and R_5 . The direction of R_4 is known and of R_5 unknown. Now choose a scale for the forces (e.g., 0.5 t to 1 cm) and construct a force polygon (Fig. 83b), starting with forces 1, 2, and 3. The construction ends with laying off the direction of force R_4 , as we do not know its magnitude (i.e., the location of point e). We do know, however, that the end of force R_5 must be at point a because, with the system in equilibrium, the force polygon must be closed.

* In this case we denote the rays Oa, Ob , etc., by numbers 12, 23, 34, and 41, as in a closed polygon we have two forces at every vertex.

To continue our solution, take a pole O and draw rays $12, 23, 34, 51$. The direction of ray 45 is unknown because we do not know the location of vertex e of the force polygon. To find this ray construct a string polygon next to the diagram in Fig. 83a, starting with point A where the force R_5 of unknown direction is applied (otherwise you will be unable to close the polygon, as A is the only known point on the action line of R_5). From point A , where force R_5 is applied, draw string 51 to its intersection with

Fig. 83.

the action line of F_1 at B , from there string 12 till its intersection with the action line of F_2 at C , string 23 till its intersection with the action line of F_3 at D , and string 34 till its intersection with the action line of R_4 at E . The closing line EA of the string polygon gives, by virtue of the conditions of equilibrium, the direction of string 45 .

In Fig. 83b we can now draw ray 45 from O parallel to EA . Its point of intersection with the direction of force 4 gives us the required vertex e of the force polygon. Vector de denotes the required force R_4 , and vector ea the required force R_5 to scale, which solves the problem.

An example of the graphical determination of the reactions of supports when the given forces are parallel is shown in Fig. 84. In this case construction of the string polygon can start at any point, as the direction of both reactions is immediately known. The required ray 45 is shown in both diagrams by a double line.

34. Graphical Analysis of Plane Trusses. A truss is a rigid structure composed of straight members connected at their ends by pins. If the members of a truss are coplanar it is called a plane truss. The points of intersection of the members are called joints. All external loads on the truss act only at the joints. In solving

trusses, the friction at the joints and the weight of the members are assumed to be negligible in comparison with the external forces and are neglected (or the weight of the members is distributed to the joints). Hence, acting on every truss member are two forces applied at its ends; being in equilibrium, the forces are directed only along the members. It follows that *the members of a truss work only in tension or in compression*. We shall restrict

Fig. 84.

ourselves to the consideration of rigid plane trusses composed of triangles. In such trusses the relation between the number of members k and the number of joints n is expressed by the equation:

$$k = 2n - 3. \quad (42)$$

In fact, any rigid triangle composed of three members has three joints (see, for example, the triangle in Fig. 85 formed by members 1, 2, 4). Each new joint requires only two new members (e.g., joint III in Fig. 85 is attached by members 3 and 5). Hence, for the remaining $(n - 3)$ joints $2(n - 3)$ members are required. The total number of members of a truss is thus $k = 3 + 2(n - 3) = 2n - 3$. A truss with fewer members will not be rigid, one with more members will be statically indeterminate.

By the solution of a truss is meant the determination of the reactions of the supports and the stresses in the members. The reactions of the forces are determined first, by either the graphical (§ 33) or analytical (§ 26) method, the truss being considered as a rigid body and its equilibrium as a whole being examined. Then the stresses in the members are determined. For this every joint is "cut out" of the truss and the equilibrium of the members attached to it is investigated, starting with a two-member joint (otherwise it would be impossible to determine the unknown stresses).

As an example let us consider the truss in Fig. 85a. It has 6 joints and 9 members. It satisfies Eq. (42) and therefore is rigid

and has no redundant members. The reactions of the supports R_1 and R_2 were determined in § 33, and forces F_1 , F_2 , F_3 are known.

Now consider the equilibrium of the members attached to joint *I* (we shall denote the joints by Roman and the members by Arabic numerals). Assume the members to be severed from the

Fig. 85.

truss*. The action of the removed portion of the truss is shown by forces S_1 and S_2 directed along members 1 and 2. We construct a closed triangle with forces R_1 , S_1 , and S_2 , which intersect at joint *I* (Fig. 85b). For this, first lay off the known force R_1 to scale and then draw through its beginning and end lines parallel to members 1 and 2. This gives us forces S_1 and S_2 acting on members 1 and 2. Now consider the equilibrium of the members attached to joint *II*. The action of the removed portion of the truss on them is denoted by

forces S'_1 , S_3 , and S_4 directed along the respective members. Force S'_1 is known from the principle of action and reaction, for $S'_1 = -S_1$. Constructing a closed triangle with the forces intersecting at joint *II* (starting with S'_1), we find the magnitudes of S_3 and S_4 (in this case $S_4 = 0$). Similarly we determine the stresses in all the other members. The force polygons for all the joints are shown in Fig. 85b. The last polygon (for joint *VI*) is constructed only to check the solution, as all the forces in it are already known.

The type of stress in each member may be determined as follows. "Cut out" a joint with portions of the members attached to it (for example, joint *III*) and apply the found forces to the sections of the members (Fig. 86). The force directed away from the joint (S_5 in Fig. 86) causes tension in the member; the force

Fig. 86.

* Fig. 86 shows the members of joint *III* severed for investigation of its equilibrium. All the other joints should be considered as cut out in the same way.

The diagram of forces for the whole truss is shown in Fig. 87b. In order to determine the stress, say, in member 1, we "cut out" joint 1 and, reading clockwise, find the name of the required force: af . In the diagram we find the vector \overline{af} and determine its magnitude. Applying now the vector to the section of member 1 (see Fig. 86) we find that the member is in compression. The same result obtains if joint 11 is cut out—only, reading clockwise, we find that the required vector is denoted by \overline{fa} . This notation of forces thus automatically takes account of the law of action and reaction.

Note the following special cases:

1) If attached to a joint not subjected to external loads are three members, two of which are collinear (joint 11 in Fig. 87a), the stress in the third member (member 4 in Fig. 87a) is zero, as can be deduced by constructing a force polygon. The member is called a *zero member*. That is why in the diagram in Fig. 87b points g and f coincide ($gf = 0$).

Fig. 88.

and type and will appear twice in the diagram, as shown in Fig. 88b. Lines de and fg denote the stress in member 1, and lines ef and gd , in member 5.

3) If in constructing a diagram you come upon a joint with more than two unknown quantities, try and construct the diagram simultaneously from two ends of the truss (if the truss is not symmetrical) or determine the stress in some members by the analytical method of sections.

In order to determine the stresses by the analytical method a section is passed through the truss, cutting three members (e.g., members 3, 4, and 2 in Fig. 87a). The equilibrium equations (35) are written for either of the truss portions, taking moments about the points where the cut members converge. If two such members are parallel Eqs. (34) will be found to be more convenient, with the components taken parallel to the axis normal to the members. This method can be used to verify the correctness or accuracy of the graphical solution of a truss for any member or joint.

Chapter 6

FRICITION

36. Laws of Static Friction. We know from experience that when two bodies tend to slide on each other a resisting force appears at their surface of contact which opposes their relative motion. This force is called static friction.

Friction is due primarily to minute irregularities on the contacting surfaces which resist their relative motion and to forces of adhesion between contacting surfaces. A detailed examination of

the nature of friction is a complex physico-mechanical problem lying beyond the scope of theoretical mechanics.

Engineering calculations are based on several general laws deduced from experimental evidence which reflect the principal features of friction with an accuracy sufficient for practical purposes. These laws, the laws of static friction, can be formulated as follows:

1. When two bodies tend to slide on each other a frictional force is developed at the surface of contact the magnitude of which can have any value from zero to a maximum value F_t which is called *limiting friction*, or *friction of impending motion*.

Frictional force is opposite in direction to the force which tends to move a body.

2. Limiting friction is equal in magnitude to the product of the coefficient of static friction (or friction of rest) f_0 and the normal pressure or normal reaction N :

$$F_t = f_0 N. \quad (43)$$

The coefficient of static friction f_0 is a dimensionless quantity which is determined experimentally and depends on the material of the contacting bodies and the conditions of the surfaces (their finish, temperature, humidity, lubrication, etc.).

3. Within fairly broad limits, the value of limiting friction does not depend on the area of the surface of contact.

Taken together, the first and second laws state that for conditions of equilibrium the static friction $F \leq F_t$, or

$$F \leq f_0 N. \quad (44)$$

The coefficient of friction can be determined experimentally by means of a simple device shown schematically in Fig. 89. The horizontal plate AB and rectangular block D are made of materials for which the coefficient of friction is to be determined. Acting on block D is the force of gravity P , which is balanced by the normal reaction of the plate N , and the applied force Q which, when the system is at rest, is balanced by the frictional force F (the scalar magnitude of Q is equal to the weight of the pan E with the weights). By gradually loading the pan we determine the load Q^* at which the block starts moving. Obviously, the limiting friction $F_t = Q^*$. Hence, as in this case $N = P$, we find from Eq. (43):

$$f_0 = \frac{F_t}{N} = \frac{Q^*}{P}.$$

Fig. 89.

A series of such experiments will demonstrate that, within certain limits of the weight P of the block, Q^* is proportional to P , and f_0 is independent of P . The coefficient of static friction f_0 is also independent of the magnitude of the area of contact, within certain limits. This confirms the validity of the 2nd and 3rd laws of friction. The validity of the 1st law follows from the fact that at any value of Q less than Q^* the block remains at rest. Hence, the frictional force F , which balances force Q , can actually assume any value from zero (at $Q=0$) to F_l (at $Q \geq Q^*$).

Attention should be called to the fact that, as long as the block remains at rest, the frictional force is equal to the applied force Q , and not to $F_l = f_0 N$. The force of friction becomes equal to $f_0 N$ only when slipping is impending.

The following table offers an idea of the values of the coefficient of static friction for various materials:

wood on wood0.4 to 0.7
metal on metal0.15 to 0.25
steel on ice0.027

For more detailed information the student is invited to consult engineering handbooks.

The foregoing refers to friction of rest. When motion occurs, the frictional force is directed opposite to the motion and equals the product of the coefficient of kinetic, or sliding, friction and the normal pressure:

$$F = fN.$$

The coefficient of kinetic friction f is also a dimensionless quantity which is determined experimentally. The value of f depends not only on the material and conditions of the contacting surfaces but also, to some degree, on the relative velocity of the bodies. In most cases the value of f at first decreases with velocity and then attains a practically constant value.

37. Reactions of Rough Constraints. Angle of Friction. Up till now, in solving problems of statics, we neglected friction and regarded the surfaces of constraints as smooth and their reactions as normal to the surface. The reactions of real (rough) constraints consist of two components: the normal reaction N and the frictional force F perpendicular to it. Consequently, the total reaction R forms an angle with the normal to the surface. As the friction increases from zero to F_l , force R changes from N to R_l , its angle with the normal increasing from zero to a maximum value φ_0 (Fig. 90). The maximum angle φ_0 which the

total reaction of a rough support makes with the normal to the surface is called the *angle of static friction*, or *angle of repose*.

From the diagram we have:

$$\tan \varphi_0 = \frac{F_t}{N}.$$

Since $F_t = f_0 N$, we have the following relation between the angle of friction and the coefficient of friction:

$$\tan \varphi_0 = f_0. \quad (45)$$

When a system is in equilibrium the total reaction R can pass anywhere within the angle of friction, depending on the applied forces. When motion impends, the angle between the reaction and the normal is φ_0 .

Fig. 90.

If to a body lying on a rough surface is applied a force P making an angle α with the normal (Fig. 91), the body will move only if the shearing force $P \sin \alpha$ is greater than $F_t = f_0 P \cos \alpha$

Fig. 91.

(neglecting the weight of the body and considering $N = P \cos \alpha$). But the inequality $P \sin \alpha > f_0 P \cos \alpha$, where $f_0 = \tan \varphi_0$, is satisfied only if $\tan \alpha > \tan \varphi_0$, i.e., if $\alpha > \varphi_0$. Consequently, if angle α is less than φ_0 the body will remain at rest no matter how great the applied force. This explains the well-known phenomena of wedging and self-locking.

38. Equilibrium with Friction. Examination of the conditions for the equilibrium of a body taking friction into account is usually limited to a consideration of the conditions when motion is impending and the frictional force acquires its maximum value F_t . For the analytical solution of problems the reaction of a rough constraint is denoted by its two components N and F_t , where $F_t = f_0 N$. The known equations of static equilibrium are then written, substituting $f_0 N$ for F_t , and solved for the required values.

If the problem requires that all possible positions of equilibrium be determined, it is sufficient to solve only for the position of impending motion. Other positions of equilibrium can then be found by reducing the coefficient of friction f_0 in the obtained solution to zero*.

* For, when motion is impending, the force of friction $F = F_t = f_0 N$. In other positions of equilibrium $F < f_0 N$; hence these positions can be found by reducing the value of f_0 in the equation $F = f_0 N$. At $f_0 = 0$ equilibrium is for the case of an absolutely smooth constraint.

It is important to note that in positions of equilibrium when motion does not impend the force of friction F is not equal to F_0 , and its magnitude, if it is required, should be determined from the conditions of equilibrium as a new unknown quantity (see second part of Problem 32).

In graphical solutions it is more convenient to denote the reaction of a rough support by a single force R , which in the position of impending motion will be inclined at an angle φ_0 to the normal to the surface.

Fig. 92.

Problem 32. A load of weight $P = 10$ kg rests on a horizontal surface (Fig. 92). Determine the force Q that should be applied at an angle $\alpha = 30^\circ$ to the horizontal to move the load from its place, if the coefficient of static friction for the surfaces of contact is $f_0 = 0.6$.

Solution. According to the conditions of the problem we have to consider the position of impending motion of the load. In this position acting on it are forces P , Q , N , and F_t . Writing the equilibrium equations in terms of the projections on the coordinate axes, we obtain:

$$Q \cos \alpha - F_t = 0; \quad N + Q \sin \alpha - P = 0.$$

From the second equation $N = P - Q \sin \alpha$, whence:

$$F_t = f_0 N = f_0 (P - Q \sin \alpha).$$

Substituting this value of F_t in the first equation, we obtain finally:

$$Q = \frac{f_0 P}{\cos \alpha + f_0 \sin \alpha} \approx 5.2 \text{ kg}.$$

If a smaller force is applied to the load, say $Q' = 4$ kg, the shearing force will equal $Q' \cos 30^\circ = 2\sqrt{3} = 3.46$ kg. The maximum friction which can develop in this case is $F_t = f_0 (P - Q' \sin 30^\circ) = 4.8$ kg, and the load will remain at rest; the friction which keeps it in equilibrium can be found from the equilibrium equations in terms of the x projections, and will be equal to the shearing force ($F' = Q' \cos 30^\circ = 3.46$ kg), and not to F_t .

Attention is drawn to the fact that in all the computations F_t should be determined from the formula $F_t = f_0 N$, N being found from the conditions of equilibrium. A frequent mistake in solving problems of this type is made in assuming $F_t = f_0 P$, though actually the pressure on the surface is not equal to the weight of the load P .

Problem 33. Determine the angle α to the horizontal at which the load on the inclined plane in Fig. 93 remains in equilibrium if the coefficient of friction is f_0 .

Solution. The problem requires that all possible positions for the equilibrium of the load be determined. For this, let us first establish the position of impending motion at which $\alpha = \alpha_t$. In that position acting on the load

Fig. 93.

are its weight P , the normal reaction N and the limiting friction F . Constructing a closed triangle with these forces, we find that $F_t = N \tan \alpha_t$. But, on the other hand, $F_t = f_0 N$. Consequently,

$$\tan \alpha_t = f_0. \quad (a)$$

In this equation α_t decreases as f_0 decreases. We conclude, therefore, that equilibrium is also possible at $\alpha < \alpha_t$. Finally, all the values of α at which the load remains in equilibrium are determined by the inequality

$$\tan \alpha \leq f_0. \quad (b)$$

If there is no friction ($f_0 = 0$), equilibrium is possible only at $\alpha = 0$. Consequently, whereas with friction equilibrium is possible at all values of the angle of inclination of the plane between zero and α_t , without friction equilibrium is possible at only one value of the angle α , which is zero. This is the difference between equilibrium with friction and the equilibrium of systems with absolutely smooth (frictionless) constraints.

The result expressed in equation (a) can be used for the determination of the coefficient of friction by finding angle α_t by experiment.

Note also that, from $f_0 = \tan \varphi_0$, where φ_0 is the angle of friction, it follows that $\alpha_t = \varphi_0$, i. e., the largest angle at which a load resting on an inclined plane remains in equilibrium (the angle of repose) is equal to the angle of friction.

Problem 34. A bent bar whose members are at right angles is constrained at A and B as shown in Fig. 94. The vertical distance between A and B is h . Neglecting the weight of the bar, determine the thickness d at which the bar with a load lying on its horizontal member will remain in equilibrium regardless of the location of the load. The coefficient of static friction of the bar on the constraints is f_0 .

Solution. Let us denote the weight of the load by P and its distance from the vertical member of the bar by l . Now consider the position of impending slip of the bar, when $d = d_t$. In this position acting on it are forces P , N , F , N' , and F' , where F and F' are the forces of limiting friction. Writing the equilibrium equations (33) and taking the moments about A , we obtain:

$$N - N' = 0, \quad F + F' - P = 0, \quad Nh - Fd_t - Pl = 0,$$

where $F = f_0 N$ and $F' = f_0 N'$. From the first two equations we find:

$$N = N', \quad P = 2f_0 N.$$

Substituting these values in the third equation and eliminating N , we have:

$$h - f_0 d_t - 2f_0 l = 0,$$

whence

$$d_t = \frac{h}{f_0} - 2l.$$

If in this equation we reduce f_0 the right-hand side will tend to infinity. Hence, equilibrium is possible at any value of $d > d_t$. The maximum value of d_t is at

Fig. 94.

$l=0$. Thus, the bar will remain in equilibrium wherever the load is placed (at $l \geq 0$) if the inequality

$$d \geq \frac{h}{f_0}$$

is satisfied. The less the friction the greater must d be. If there is no friction ($f_0=0$) equilibrium is obviously impossible, as $d=\infty$.

Here now is a graphical solution of the problem. Instead of the normal reactions and the frictional forces we denote at points A and B the total reactions R_A and R_B whose angles with the normals in the condition of impending slip will be equal to the angle of friction φ_0 (Fig. 94b). Thus, acting on the bar are three forces R_A , R_B , and P . For equilibrium they must all intersect at K , where forces R_A and R_B intersect. We obtain the equation $h = (l + d_l) \tan \varphi_0 + l \tan \varphi_0$, which could be expected from an examination of the diagram, or $h = (2l + d_l) f_0$, as $\tan \varphi_0 = f_0$. Thus we obtain the same result for d_l as in the analytical solution.

The problem offers an example of a self-locking device which is often used in practice.

Problem 35. Neglecting the weight of the ladder AB in Fig. 95, determine the values of angle α at which a man can climb to the top of the ladder at B if the angle of friction for the contacts at the floor and the wall is φ_0 .

Solution. Let us examine the position of impending slip of the ladder by the graphical method. For impending motion the forces acting on the ladder are the reactions of the floor and wall R_A and R_B which are inclined at the angle of friction φ_0 to the normals to the surfaces. The action lines of the reactions intersect at K . Thus, for the system to be in equilibrium the third force P (the weight of the man) acting on the ladder must also pass through K . Hence, in the position shown in the diagram the man cannot climb higher than D . For him to reach B the action lines of R_A and R_B must intersect somewhere along BO , which is possible only if force R_A is directed along AB , i.e., when $\alpha \leq \varphi_0$.

Thus a man can climb to the top of a ladder only if its angle with the wall does not exceed the angle of friction with the floor. The friction on the wall is irrelevant, i.e., the wall may be smooth.

39. Belt Friction. A force P is applied at the end of a string passing over a cylindrical shaft (Fig. 96). Let us determine the least force Q that must be applied at the other end of the string to maintain equilibrium.

Consider the equilibrium of an element DE of the string of length $dl = R d\theta$, where R is the radius of the shaft. The difference dT between the tensions in the string at D and E is balanced by the frictional force $dF = f_0 dN$ (dN is the normal reaction), since at the lowest value of Q motion is impending. Consequently,

$$dT = f_0 dN.$$

The value of dN is determined from the equilibrium equation derived for the force components parallel to axis Oy . The sine of a very small angle approxi-

Fig. 95.

Fig. 96.

mately equals the angle itself, and, neglecting small quantities of higher order, we have:

$$dN = T \sin \frac{d\theta}{2} + (T + dT) \sin \frac{d\theta}{2} = 2T \frac{d\theta}{2} = T d\theta.$$

Substituting this value of dN in the preceding equation we obtain:

$$dT = f_0 T d\theta.$$

Dividing both members of the equation by T and integrating the right-hand member in the interval from 0 to α and the left-hand member from Q to P (as the tensions in the string are Q at the point where $\theta = 0$, and P at the point where $\theta = \alpha$), we obtain:

$$\int_Q^P \frac{dT}{T} = f_0 \int_0^\alpha d\theta \quad \text{or} \quad \ln \frac{P}{Q} = f_0 \alpha,$$

from which it follows that $P/Q = e^{f_0 \alpha}$, or

$$Q = P e^{-f_0 \alpha}. \quad (46)$$

We see that the required force Q depends only on the coefficient of friction f_0 and the angle α ; it does not depend on the radius of the shaft. If there is no friction ($f_0 = 0$), we have, as could be expected, $Q = P$. Of great practical importance is the fact that by increasing angle α (wrapping the string around the shaft) it is possible substantially to reduce the force Q required to balance force P . Table 1 shows, for example, that a tension of one ton can be supported by only 2 kg by wrapping a hemp rope twice about a wooden post.

Eq. (46) also gives the relation between the tensions in the driving part (P) and the driven part (Q) of a belt uniformly rotating a pulley without slippage. Assuming, for instance, $\alpha = \pi$ and, for a leather belt on a cast-iron pulley, $f_0 = 0.3$ the ratio of the tensions $Q/P = e^{-0.3\pi} \approx 0.4$.

Table 1
VALUES FOR Q/P AT $f_0 = 0.5$
(Hemp Rope on Wood)

Number of Turns	α	$Q/P = e^{-f_0 \alpha}$
$1/2$	π	0.208
1	2π	0.043
$1 1/2$	3π	0.009
2	4π	0.002

Fig. 97.

Problem 36. A force F is applied to the lever DE of the band-brake in Fig. 97. Determine the frictional torque M_T exerted on the drum of radius R , if $CD = 2CE$ and the coefficient of friction of the band on the drum is $f_0 = 0.5$.

Solution. Acting on the drum and band AB wrapped around it is a force P (evidently $P = 2F$) applied at A and a force Q applied at B which is

determined by Eq. (46). We also have $f_0 = 0.5$ and $\alpha = \frac{5}{4}\pi = 3.93$ radians. Hence,

$$Q = 2Fe^{-\frac{5}{4}\pi} \approx 0.28F.$$

The required torque is

$$M_T = (P - Q)R = 1.72FR \text{ kg-m.}$$

The less the value of Q , i.e., the greater the coefficient of friction f_0 and the angle α , the greater the torque.

40. Rolling Friction and Pivot Friction. Rolling friction is defined as the resistance offered by a surface to a body rolling on it.

Consider a roller of radius R and weight P resting on a rough horizontal surface (Fig. 98a). If we apply to the axle of the roller a force $Q < F$, there will be developed at A a frictional force F , equal in magnitude to Q , which prevents the roller from slipping on the surface. If the normal reaction N is also assumed to be applied at A , it will balance force P , with forces Q and F making a couple which turns the roller. If these assumptions were correct we could expect the roller to move, however small the force Q .

Fig. 98.

Experience tells us, however, that this is not the case; for, due to deformation, the bodies contact over a certain surface AB (Fig. 98b). The action of force Q tends to shift a portion of the load from A to B . As a result, the reaction N is shifted in the direction of the action of force Q . As Q increases this displacement grows till it reaches a certain limit k . Thus, in the position of impending motion, acting on the roller will be a couple (Q, F) of moment $Q_i R$ balanced by a couple (N, P) of moment Nk . As the moments are equal we have $Q_i R = Nk$, or

$$Q_i = \frac{k}{R} N. \quad (47)$$

As long as $Q < Q_i$ the roller remains at rest; when $Q > Q_i$ it starts to roll.

The linear quantity k in Eq. (47) is called *the coefficient of rolling friction, or resistance*, and is generally expressed in centimetres. The value of k depends on the material of the bodies and is determined experimentally. The following list offers an idea of some typical values of k :

Wood on wood	0.05 to 0.08 cm
Mild steel on steel (wheel on rail)	0.005 cm
Hardened steel on steel (ball bearing)	0.001 cm

The ratio k/R for most materials is much less than the coefficient of static friction f_s . That is why in mechanisms rolling parts (wheels, rollers, ball bearings, etc.) are preferred to sliding parts.

Problem 37. Determine the values of angle α at which a cylinder of radius R will remain at rest on an inclined plane if the coefficient of rolling friction is k (Fig. 99).

Solution. Consider the position of impending motion, when $\alpha = \alpha_1$. Resolving force P into rectangular components P_1 and P_2 , we find that the moving force $Q_1 = P_1 = P \sin \alpha_1$, and the normal reaction $N = P_2 = P \cos \alpha_1$. From Eq. (47) we have:

$$P \sin \alpha_1 = \frac{k}{R} P \cos \alpha_1,$$

or

$$\tan \alpha_1 = \frac{k}{R}.$$

If k tends to zero the value of α_1 also tends to zero. We conclude from this that equilibrium is maintained at any angle $\alpha < \alpha_1$. This result may be used for determining coefficient k by experimentally finding angle α_1 .

Concept of Pivot Friction. Consider a sphere at rest on a horizontal plane. If a horizontal couple of moment M is applied to the sphere it will tend to rotate the sphere about its vertical axis. We know from experience that the sphere will start turning only when M exceeds some specific value M_L which is determined by the equation

$$M_L = \lambda N, \quad (48)$$

where N is the normal pressure of the sphere on the surface—in this case equal to the sphere's weight. This result is explained by the development of so-called pivot friction, i.e., resistance to rotation due to the friction of the sphere on the surface. This is the type of friction developed in step bearings (pivots). The factor λ in Eq. (48) is a linear quantity called the *coefficient of pivot friction*. The value of λ is very small (one-fifth to one-tenth of the coefficient of rolling friction k).

Fig. 99.

Chapter 7

COUPLES AND FORCES IN SPACE*

41. Moment of a Force About a Point as a Vector. Before proceeding with the solution of problems of statics for force systems in space, we should elaborate some of the concepts introduced before. Let us begin with the concept of moment of a force.

* The student who is interested only in the methods of solving problems involving the equilibrium of bodies subjected to non-coplanar force systems may leave out §§44-47, which deal with the reduction of couples and forces in space.

1. **Vector Expression of a Moment.** The moment of a force \mathbf{F} about a centre O (see Fig. 100), as a measure of the tendency of that force to turn a body, is characterised by the following three elements: 1) magnitude of the moment, which is equal to the product of the force and the moment arm, i.e., Fh ; 2) the plane of rotation OAB through the line of action of the force \mathbf{F} and the centre O ; and 3) the sense of the rotation in that plane. When all the given forces and the centre O are coplanar there is no need to specify the plane of rotation, and the moment can be

Fig. 100.

be defined as a scalar algebraic quantity equal to $\pm Fh$, where the sign indicates the sense of rotation (see § 14).

If, however, the given forces are not coplanar, the planes of rotation have different aspects for different forces and have to be specified additionally. The position of a plane in space (its aspect) can be specified by specifying a line (vector) normal to it. If, furthermore, the modulus of this vector is taken as representing the magnitude of the force moment, and the direction of the vector

is made to denote the sense of rotation, such a vector completely specifies the three elements which characterise the moment of a force with respect to a given centre O .

Thus, in the general case we shall denote the moment $m_O(\mathbf{F})$ of a force \mathbf{F} about a point O (Fig. 100) by a vector \mathbf{M}_O applied at O , equal in magnitude (to some scale) to the product of the force F and the moment arm h , and normal to the plane OAB through O and \mathbf{F} . We shall direct vector \mathbf{M}_O so that the rotation viewed from the arrowhead is observed as counterclockwise. Vector \mathbf{M}_O will thus specify the magnitude of the moment, the plane of rotation OAB , which may be different for different forces, and the sense of rotation in that plane. The point at which vector \mathbf{M}_O is applied defines the position of the moment centre.

2. **Expression of Moment of a Force in Terms of a Vector (Cross) Product.** Consider the cross product of vectors \overrightarrow{OA} and \mathbf{F} (Fig. 100). From the definition*,

$$|\overrightarrow{OA} \times \mathbf{F}| = 2 \text{ areas of } \triangle OAB = M_O,$$

* The cross product $\mathbf{a} \times \mathbf{b}$ of vectors \mathbf{a} and \mathbf{b} is itself a vector \mathbf{c} equal in magnitude to the area of a parallelogram constructed with vectors \mathbf{a} and \mathbf{b} as its sides. Vector \mathbf{c} is perpendicular to the plane through the two vectors in the direction from which a counterclockwise rotation would be seen to carry \mathbf{a} into \mathbf{b} through the smaller of the angles between them.

as vector M_O is equal in magnitude to twice the area of triangle OAB . Vector $(\overline{OA} \times \mathbf{F})$ is perpendicular to plane OAB in the direction from which a counterclockwise rotation would be seen to carry \overline{OA} into \mathbf{F} through the smaller angle between them (when the two forces are laid off from the same point), i.e., it is in the same direction as vector M_O . Hence, vectors $(\overline{OA} \times \mathbf{F})$ and M_O are equal in magnitude and direction and, as can be readily verified, in dimension also, i.e., they both denote the same quantity. Therefore,

$$M_O = \overline{OA} \times \mathbf{F} \text{ or } M_O = \mathbf{r} \times \mathbf{F}, \quad (49)$$

where vector $\mathbf{r} = \overline{OA}$ is the radius vector from O to A .

Thus, the moment of a force \mathbf{F} about a centre O is equal to the cross product of the radius vector $\mathbf{r} = \overline{OA}$ from O to the point of application A of the force, and the force itself. This expression of moment of a force will be found convenient in proving some theorems.

42. Moment of a Force with Respect to an Axis. Before proceeding with the solution of problems of statics for any force system in space we must introduce the concept of moment of a force about an axis.

The moment of a force about an axis is a measure of the tendency of the force to produce rotation about that axis. Consider a rigid body free to rotate about an axis z (Fig. 101). Let a force \mathbf{F} applied at A be acting on the body. Let us now pass a plane xy through point A normal to the axis z and let us resolve the force \mathbf{F} into rectangular components \mathbf{F}_z parallel to the z axis and \mathbf{F}_{xy} in the plane xy (\mathbf{F}_{xy} is in fact the projection of force \mathbf{F} on the plane xy). Obviously, force \mathbf{F}_z , being parallel to axis z , cannot turn the body about that axis (it only tends to translate the body *along* it). Thus we find that the total tendency of force \mathbf{F} to rotate the body is the same as that of its component \mathbf{F}_{xy} . We conclude, then, that

$$m_z(\mathbf{F}) = m_z(\mathbf{F}_{xy}), \quad (50)$$

where $m_z(\mathbf{F})$ denotes the moment of force \mathbf{F} with respect to axis z .

But the rotational effect of force \mathbf{F}_{xy} , which lies in a plane perpendicular to axis z , is the same whether considered with respect to

Fig. 101.

axis z or to point O , where the axis pierces the plane xy . Hence, $m_z(\mathbf{F}_{xy}) = m_O(\mathbf{F}_{xy})$ or, by Eq. (50)*,

$$m_z(\mathbf{F}) = m_O(\mathbf{F}_{xy}) = \pm F_{xy}h. \quad (51)$$

From this we deduce the following definition: *The moment of a force about an axis is a scalar quantity equal to the moment of the projection of that force on a plane normal to the axis with respect to the point of intersection of the axis and the plane.*

We shall call a moment positive if the rotation induced by force \mathbf{F}_{xy} is seen as counterclockwise when viewed from the positive end of the axis, and negative if it is seen as clockwise.

Fig. 102.

It is evident from Fig. 101 that in computing a moment according to Eq. (51) plane xy may pass through any point on the axis z . Thus, in order to determine the moment of a force about axis z in Fig. 102 we have to: 1) pass an arbitrary plane xy normal to the axis;

2) project force \mathbf{F} on the plane and compute the magnitude of \mathbf{F}_{xy} ; 3) erect a perpendicular from point O , where the plane and axis intersect, to the action line of \mathbf{F}_{xy} and determine its length h ; 4) compute the product $F_{xy}h$; 5) determine the sense of the moment.

In determining moments the following special cases should be borne in mind:

1) If a force is parallel to an axis, its moment about that axis is zero (since $F_{xy} = 0$).

2) If the line of action of a force intersects with the axis, its moment with respect to that axis is zero (since $h = 0$).

Combining the two cases, we conclude that *the moment of a force with respect to an axis is zero if the force and the axis are coplanar.*

3) If a force is perpendicular to an axis, its moment about that axis is equal to the product of the force magnitude and the perpendicular distance from the force to the axis.

Problem 38. Determine the moments with respect to the coordinate axes of forces \mathbf{P} and \mathbf{Q} acting on a horizontal plate as shown in Fig. 103.

Solution. 1) Force \mathbf{P} is parallel to the z axis, perpendicular to the x and y axes, and passes at a distance of $b/2$ and $a/2$ from them respectively. Hence, taking into account the signs,

$$m_x(\mathbf{P}) = -P \frac{b}{2}, \quad m_y(\mathbf{P}) = P \frac{a}{2}, \quad m_z(\mathbf{P}) = 0.$$

* The symbol $m_O(\mathbf{F})$, which we used for coplanar force systems and which we shall continue to use, denotes the scalar (algebraic) magnitude of the moment.

2) To determine $m_x(Q)$, project force Q on the yz plane. We obtain:

$$Q_{yz} = Q \sin \alpha.$$

The moment arm of force Q_{yz} with respect to O is b and the rotation induced by it, when observed from the end of the x axis, is counterclockwise. Consequently,

$$m_x(Q) = bQ \sin \alpha.$$

Now let us determine $m_y(Q)$. Force Q lies in plane ABD , which is normal to the y axis and intersects it at B . Consequently, $Q_{xz} = Q$. Erecting a perpendicular from B to the action line of Q (see supplementary diagram in Fig. 103), we find that it is of length $h = a \sin \alpha$. Finally, taking into account the sense of rotation, we obtain

$$m_y(Q) = -Qa \sin \alpha.$$

To determine $m_z(Q)$, we project force Q on the xy plane and find that $Q_{xy} = Q \cos \alpha$, and that the moment arm of Q_{xy} with respect to O is b . Hence, taking into account the sign,

$$m_z(Q) = bQ \cos \alpha.$$

Fig. 103.

Analytical Expression of the Moment of a Force about the Coordinate Axes. Consider a rectangular coordinate system with an arbitrary origin O (Fig. 104) and a force F applied at a point A whose coordinates are x, y, z . Let us compute analytically the moment of force

F with respect to the z axis. For this we project force F on the xy plane and resolve the projection F_{xy} into rectangular components F_x and F_y . These components are, obviously, equal in magnitude to the projections of the force F on the x and y axes. But, from the definition,

$$m_z(F) = m_O(F_{xy}) = m_O(F_x) + m_O(F_y),$$

which also follows from Varignon's theorem. Also, from the diagram, $m_O(F_x) = -yF_x$ and $m_O(F_y) = xF_y$. Hence,

$$m_z(F) = xF_y - yF_x.$$

We obtain the moments about the other two axes in the same way, and finally,

$$\left. \begin{aligned} m_x(\mathbf{F}) &= yF_z - zF_y, \\ m_y(\mathbf{F}) &= zF_x - xF_z, \\ m_z(\mathbf{F}) &= xF_y - yF_x. \end{aligned} \right\} \quad (52)$$

Eqs. (52) give the *analytical expression* of the moments of a force about the axes of a cartesian coordinate system. Using these equations, we can determine the moments if we know the projections of a force on the coordinate axes and the coordinates of its point of application.

Problem 39. Compute analytically the moments of force \mathbf{Q} in Fig. 103 with respect to the coordinate axes.

Solution. Force \mathbf{Q} is applied at a point A whose coordinates are $x=a$, $y=b$, $z=0$. Its projections on the coordinate axes are

$$Q_x = -Q \cos \alpha, \quad Q_y = 0, \quad Q_z = Q \sin \alpha.$$

Substituting these expressions in Eqs. (52), we have:

$$m_x(\mathbf{Q}) = bQ \sin \alpha, \quad m_y(\mathbf{Q}) = -aQ \sin \alpha, \quad m_z(\mathbf{Q}) = bQ \cos \alpha.$$

43. Relation Between the Moments of a Force about a Point and an Axis. Consider a force \mathbf{F} acting on a body at a point A (Fig. 105). Let us draw an axis z and take an arbitrary point O on it. The moment of \mathbf{F} about O is denoted by a vector \mathbf{M}_O , normal to plane OAB , of scalar magnitude

$$M_O = Fh = 2 \text{ areas } \triangle OAB.$$

Drawing now a plane xy through O normal to axis z and projecting force \mathbf{F} on it, we find from Eq. (51) that

$$m_z(\mathbf{F}) = m_O(\mathbf{F}_{xy}) = 2 \text{ areas } \triangle OA_1B_1.$$

But triangle OA_1B_1 is the projection of triangle OAB on the

plane xy . The angle between the planes of the two triangles is equal to the angle between the normals to the two planes, i.e., γ . Then, from the well-known geometric formula, area $\triangle OA_1B_1 = \text{area } \triangle OAB \cos \gamma$.

Doubling both sides of the equation and observing that twice the areas of triangles OA_1B_1 and OAB are respectively equal to $m_z(\mathbf{F})$ and M_O , we obtain finally:

$$m_z(\mathbf{F}) = M_O \cos \gamma. \quad (53)$$

Fig. 105.

As the product $M_O \cos \gamma$ gives the projection of vector $M_O = m_O(F)$ on axis z , Eq. (53) may also be written in the form:

$$m_z(F) = M_z \quad \text{or} \quad m_z(F) = [m_O(F)]_z. \quad (54)$$

We have thus proved the following relation between the moment of a force about an axis and its moment about a point on that axis: *The moment of a force F with respect to an axis is equal to the projection on that axis of the vector denoting the moment of that force with respect to any point on the given axis.*

44. Vector Expression of the Moment of a Couple. The action of a couple on a body is characterised by: 1) the magnitude of the moment of the couple, 2) the aspect of the plane of action, and 3) the sense of the rotation in that plane. In considering couples in space all three characteristics must be specified in order to define any couple. This can be done if, by analogy with the moment of a force, the moment of a couple is denoted by a vector \mathbf{m} or \mathbf{M} whose modulus (to some scale) is equal to the magnitude of the moment of that couple, i.e., the product of one of its forces and the moment arm. The vector is normal to the plane of action of the couple in the direction from which the rotation induced by the couple would be observed as counterclockwise (Fig. 106).

Fig. 106.

Since a couple may be located anywhere in its plane of action or in a parallel plane (see § 19), it follows that vector \mathbf{m} can be attached to any point of the body (such a vector is known as a *free vector*):

It is evident that vector \mathbf{m} does, in fact, define the given couple as, if we know \mathbf{m} , by passing an arbitrary plane normal to \mathbf{m} we obtain the plane of action of the couple; by measuring the length of \mathbf{m} we obtain the magnitude of the couple moment; and the direction of \mathbf{m} shows the sense of rotation of the couple.

In magnitude the moment of a couple is equal to the moment of one of its forces with respect to the point of application of the other force, i.e., $m = m_B(F)$; the two vectors have the same direction (compare Figs 106 and 100). Consequently,

$$\mathbf{m} = \mathbf{m}_B(F) = \mathbf{m}_A(F').$$

45. Composition of Couples in Space. Conditions of Equilibrium of Couples. Couples in space are compounded according to the

following theorem: *Any system of couples acting on a rigid body is equivalent to a single couple of moment equal to the geometrical sum of the moments of the component couples.*

Let us first prove the theorem for two couples of moments m_1 and m_2 acting on a body in planes (I) and (II) (Fig. 107). Take on the line of intersection of the two planes a segment $AB = d$. By virtue of the properties of couples proved in § 19, we can represent the couple of moment m_1 in terms of forces F_1 and F'_1 , and the couple of moment m_2 in terms of forces F_2 and F'_2 applied at points A and B respectively. Evidently, $F_1 d = m_1$ and $F_2 d = m_2$.

Fig. 107.

By compounding the forces applied at points A and B we ascertain that couples (F_1, F'_1) and (F_2, F'_2) are really replaced by (R, R_1) . Let us determine the moment M of this couple. As $R = F_1 + F_2$, and the moment of a couple is equal to the moment of one of its forces with respect to the point of application of the other force, we obtain from Eq. (49):

$$M = \overline{AB} \times R = \overline{AB} \times (F_1 + F_2) = (\overline{AB} \times F_1) + (\overline{AB} \times F_2).$$

But $\overline{AB} \times F_1 = m_1$ and $\overline{AB} \times F_2 = m_2$. Hence,

$$M = m_1 + m_2, \quad (55)$$

i.e., vector M is represented by the diagonal of a parallelogram with vectors m_1 and m_2 as its sides, which proves the theorem for two couples.

If there are n couples of moments m_1, m_2, \dots, m_n acting on a body, we can apply Eq. (55) successively with the result that we shall have replaced a system of couples by a single couple of moment

$$M = m_1 + m_2 + \dots + m_n = \sum m_k. \quad (56)$$

Vector M can be determined as the closing side of a polygon constructed with the component vectors as its sides.

If the component vectors are non-coplanar, the problem is best solved by the analytical method. For this draw a coordinate system. From the theorem of the projection of a vector sum on an axis, and from Eq. (56), we have:

$$M_x = \sum m_{kx}, \quad M_y = \sum m_{ky}, \quad M_z = \sum m_{kz}. \quad (57)$$

With these projections we can construct vector M . Its magnitude is given by the expression

$$M = \sqrt{M_x^2 + M_y^2 + M_z^2}.$$

The above results readily give the conditions for the equilibrium of a system of couples acting on a rigid body. Any system of couples can be reduced to a single couple of moment determined by Eq. (56), but for equilibrium we must have $M=0$, or

$$\sum m_k = 0,$$

i.e., the polygon constructed with the moment vectors of the component couples acting on a body must be closed.

The analytical conditions of equilibrium can be found if we take into account that $M=0$ only if $M_x=0$, $M_y=0$, and $M_z=0$. This, by virtue of Eqs. (57), is possible if

$$\sum m_{kx} = 0, \quad \sum m_{ky} = 0, \quad \sum m_{kz} = 0. \quad (58)$$

In conclusion it should be noted that if all the couples lie in the same or in parallel planes, the vectors of their moments will be collinear and their composition is reduced to an algebraic operation. This result was obtained in § 20.

Fig. 108.

Fig. 109.

Problem 40. Acting on a rigid body are two couples in mutually perpendicular planes (Fig. 108). The moment of each is 3 kg-m. Determine the resultant couple.

Solution. Denote the moments of the two couples by vectors m_1 and m_2 applied at an arbitrary point A ; the moment of the resultant couple is denoted by the vector m . The resultant couple is located in plane $ABCD$ normal to m and the magnitude of the resultant moment is $3\sqrt{2}$ kg-m.

If the sense of rotation of one of the given couples is reversed, the resultant couple will occupy a plane normal to $ABCD$.

Problem 41. The cube in Fig. 109 hangs from two vertical rods AA_1 and BB_1 so that its diagonal AB is horizontal. Applied to the cube are couples (P, P') and (Q, Q') . Neglecting the weight of the cube, determine the relation between forces P and Q at which it will be in equilibrium and the reactions of the rods.

Solution. The system of couples (P, P') and (Q, Q') is equivalent to a couple and can be balanced only by a couple. Hence, the required reactions N and N' must form a couple. Let us denote its moment m normal to diagonal AB as shown in the diagram. In scalar magnitude $m = Na\sqrt{2}$, where a is the length of the edge of the cube. Denote the moments of the given couples by the symbols m_1 and m_2 ; their scalar magnitudes are $m_1 = Pa$ and $m_2 = Qa$ and their directions are as shown.

Now draw a coordinate system and write the equilibrium equations (58):

$$\sum m_{kx} = m_2 - m \cos 45^\circ = 0, \quad \sum m_{ky} = m_1 - m \cos 45^\circ = 0.$$

The third condition is satisfied similarly.

It follows from the obtained equations that we must have $m_1 = m_2$, i.e., $Q = P$. We find, further, that

$$m = \frac{m_1}{\cos 45^\circ} = m_1 \sqrt{2} = Pa \sqrt{2}.$$

But $m = Na\sqrt{2}$, hence $N = P$.

Thus, equilibrium is possible when $Q = P$. The reactions of the rods are equal to P in magnitude and are directed as shown.

46. Reduction of a Force System in Space to a Given Centre.

The results obtained above make it possible to solve the problem of reducing an arbitrary force system to a given centre. This problem, which is analogous to the one examined in § 22, is solved by applying the theorem of the translation of a force to a parallel position. In order to transfer a force F acting on a rigid body from a point A (Fig. 110a) to a point O , we apply at O forces

$F' = F$ and $F'' = -F$. Force $F' = F$ will be applied at O together with the couple (F, F'') of moment m , which can also be shown as in Fig. 110b. We have:

$$m = m_O(F). \quad (59)$$

Consider now a rigid body on which an arbitrary system of forces F_1, F_2, \dots, F_n is acting (Fig. 111a). Take any point O as the centre of reduction and transfer all the forces of the system to it, adding the corresponding couples. We have then acting on the body a system of forces

$$F'_1 = F_1, \quad F'_2 = F_2, \quad \dots, \quad F'_n = F_n \quad (60)$$

Fig. 110.

applied at O and a system of couples whose moments, by Eq. (59), are:

$$m_1 = m_O(F_1), \quad m_2 = m_O(F_2), \quad \dots, \quad m_n = m_O(F_n). \quad (61)$$

The forces applied at O can be replaced by a single force R applied at the same point. Its magnitude is $R = \sum F_k$, or, by Eqs. (60)

$$R = \sum F_k. \quad (62)$$

We can compound all the obtained couples by geometrically adding the vectors of their moments. The system of couples will be replaced by a couple of moment $M_O = \sum m_k$, or, by Eqs. (61),

$$M_O = \sum m_O(F_k). \quad (63)$$

As in the case of a coplanar system, the quantity R (the geometrical sum of all the forces) is called the *principal vector* of the system; vector M_O (the geometrical sum of the

Fig. 111.

moments of all the forces with respect to O) is called the *principal moment* of the system with respect to O .

We have thus proved the following theorem: Any system of forces acting on a rigid body can be reduced to an arbitrary centre O and replaced by a single force R , equal to the principal vector of the system applied at the centre of reduction, and a moment M_O , equal to the principal moment of the system with respect to O (Fig. 111b).

Vectors R and M_O are usually determined analytically, i.e., according to their projections on the coordinate axes.

We know the expressions of R_x , R_y and R_z from § 10. We shall denote the projections of M_O on the coordinate axes by the symbols M_x , M_y , M_z . From the theorem of the projection of a vector sum on an axis we have $M_x = \sum [m_O(F_k)]_x$, or, from Eq. (54), $M_x = \sum m_x(F_k)$. Similarly we obtain M_y and M_z .

Thus the formulas for determining the projections of the principal vector R and the principal moment M_O are:

$$R_x = \sum F_{kx}, \quad R_y = \sum F_{ky}, \quad R_z = \sum F_{kz}; \quad (64)$$

$$M_x = \sum m_x(F_k), \quad M_y = \sum m_y(F_k), \quad M_z = \sum m_z(F_k). \quad (65)$$

It follows from this theorem that two systems of forces, for which \mathbf{R} and \mathbf{M}_O are the same, are statically equivalent. Hence, to define a force system acting on a rigid body it is sufficient to define its principal vector and its principal moment with respect to a given centre, i.e., to specify the six quantities in Eqs. (64) and (65).

Problem 42. Determine the stresses in section AA_1 of a beam subjected to forces as shown in Fig. 112a. Force Q goes through the centre of the right-hand portion of the beam; force F lies in the plane Oxz ; force P is parallel to the y axis.

Fig. 112.

Solution. The required stresses are determined as in Problem 18 (§ 22). For this reduce all the forces to the centre O of the section, and place the origin of the coordinate system there. Applying Eqs. (64) and (65) to determine the principal vector and principal moment of the system, we have:

$$R_x = F \sin \alpha - Q, \quad R_y = -P, \quad R_z = F \cos \alpha;$$

$$M_x = bP, \quad M_y = bF \sin \alpha - \frac{b}{2} Q, \quad M_z = \frac{h}{2} P.$$

Thus, acting on the section AA_1 are two lateral forces R_x and R_y , an axial tension R_z , and three couples of moments M_x , M_y , and M_z (Fig. 112b): the first two tend to bend the beam about axes Ox and Oy and the last tends to twist it about axis Oz .

47. Reduction of a Force System in Space to the Simplest Possible Form. The theorem proved in § 46 makes it possible to establish the simplest form to which a given force system in space can be reduced. For this it is necessary to determine the principal vector and principal moment of the system with respect to an arbitrary point and investigate the result.

The following cases are possible:

1) If $\mathbf{R} = 0$ and $\mathbf{M}_O = 0$, the system is in equilibrium. This case will be examined in § 48.

2) If $\mathbf{R} = 0$ and $\mathbf{M}_O \neq 0$, the system can be reduced to a couple of moment computed according to Eqs. (65). A free body subjected to the action of such a force system can be (though not always) in pure rotational motion.

3) If $R \neq 0$ and $M_O = 0$, the system can be reduced to a resultant R passing through point O . The magnitude of R is computed according to Eqs. (64).

A free body subjected to the action of such a force system can be in pure translatory motion (if the resultant R passes through the centre of gravity of the body).

4) If $R \neq 0$ and $M_O \neq 0$, and $M_O \perp R$, the system can be reduced to a single resultant R not passing through point O .

For if $M_O \perp R$, the couple denoted by vector M_O , and force R are coplanar (Fig. 113). If we take the couple forces R' and R'' equal in magnitude to R and place them as shown

Fig. 113.

in Fig. 113, we obtain forces R and R'' which cancel each other, and the system is replaced by a resultant $R' = R$ through point O' (see § 23, case 3b). The distance OO' ($OO' \perp R$) is determined from Eq. (31), where $d = OO'$.

It will be readily noticed that this case applies, in particular, to any system of parallel forces or coplanar forces whose principal vector $R \neq 0$.

5) If $R \neq 0$ and $M_O \neq 0$, and vector M_O is parallel to R (Fig. 114a), the system can be reduced to a resultant force R and a couple (P, P') in a plane normal to the resultant force (Fig. 114b). Such a force-and-couple system is called a *wrench*; the line of action of force R is the *axis of the wrench*. No further

Fig. 114.

reduction of the system is possible. For, though the system will not change if the couple is transferred, if force R is transferred from centre O to any point C , there will be added perpendicular to the moment M_O a moment $M'_C = m_C(R)$, and the moment $M_C = M_O + M'_C$ of the resulting couple will increase. Thus, this type of force system cannot be reduced to a single resultant or to a single couple. A free rigid body subjected to the action of such a force system can perform only a compound (screw) motion.

If one of the forces of the couple, say P' , is added to force R , the given system can be replaced by two non-coplanar forces Q and P (Fig. 115). As the new force system is equivalent to a wrench, it also has no resultant.

6) If $\mathbf{R} \neq 0$ and $\mathbf{M}_O \neq 0$ and vectors \mathbf{M}_O and \mathbf{R} are neither perpendicular nor parallel, the system can be reduced to a wrench whose axis does not pass through point O .

To prove this, let us resolve vector \mathbf{M}_O into two components, \mathbf{M}_1 along \mathbf{R} , and \mathbf{M}_2 perpendicular to \mathbf{R} (Fig. 116). We have $M_1 = M_O \cos \alpha$ and $M_2 = M_O \sin \alpha$, where α is the angle between vectors \mathbf{M}_O and \mathbf{R} . The couple denoted by the vector \mathbf{M}_2 ($\mathbf{M}_2 \perp \mathbf{R}$) and force \mathbf{R} can be replaced, as in the case shown in Fig. 113, with a single resultant \mathbf{R}' applied at point O' . As a result, the given system is replaced by a force $\mathbf{R}' = \mathbf{R}$ and a couple of moment \mathbf{M}_1 parallel to \mathbf{R}' , i.e., a wrench whose axis passes through point O' .

Fig. 115.

Fig. 116.

48. Condition of Equilibrium of an Arbitrary Force System in Space. The Case of Parallel Forces. Like a coplanar force system, any force system in space can be reduced to a point O and replaced by a resultant force \mathbf{R} and couple of moment \mathbf{M}_O [the values of \mathbf{R} and \mathbf{M}_O are determined from Eqs. (62) and (63)]. Reasoning as in the beginning of § 24, we come to the conclusion that the necessary and sufficient conditions for the given system of forces to be in equilibrium are that $\mathbf{R} = 0$ and $\mathbf{M}_O = 0$. But vectors \mathbf{R} and \mathbf{M}_O can be zero only if all their projections on the coordinate axes are zero, i.e., when $R_x = R_y = R_z = 0$ and $M_x = M_y = M_z = 0$, or, by Eqs. (64) and (65), when the acting forces satisfy the conditions

$$\left. \begin{aligned} \sum F_{kx} &= 0, & \sum F_{ky} &= 0, & \sum F_{kz} &= 0; \\ \sum m_x(F_k) &= 0, & \sum m_y(F_k) &= 0, & \sum m_z(F_k) &= 0. \end{aligned} \right\} \quad (66)$$

Thus, the necessary and sufficient conditions for the equilibrium of any force system in space are that the sums of the projections of all the forces on each of three coordinate axes and the sums of the moments of all the forces about those axes must separately vanish*.

* In writing conditions (66) you may take, if you find it expedient, one coordinate system to compute the force projections and another to compute the moments.

Eqs. (66) express the simultaneously necessary conditions for the equilibrium of any rigid body subjected to the action of any force system in space. The first three of the equations express the conditions necessary for the body to have no translatory motion parallel to the coordinate axes; the latter three equations express the conditions of no rotation about the axes.

If, besides forces, there is also a couple defined by its moment M acting on a body, the form of the first three of Eqs. (66) will remain the same (the sum of the projections of the forces of a couple on any axis is zero), but the last three equations will take the following form:

$$\sum m_x(F_k) + M_x = 0, \quad \sum m_y(F_k) + M_y = 0, \quad \sum m_z(F_k) + M_z = 0. \quad (67)$$

The Case of Parallel Forces. If all the forces acting on a body are parallel, the coordinate axes can be chosen so that the z axis is parallel to the forces (Fig. 117). Then the x and y projections of all the forces will be zero, their moments about the z axis will be zero, and the Eqs. (66) will be reduced to three conditions of equilibrium:

$$\begin{aligned} \sum F_{kz} &= 0, & \sum m_x(F_k) &= 0, \\ \sum m_y(F_k) &= 0. \end{aligned} \quad (68)$$

Fig. 117.

The other equations will turn into identities $0=0$.

Thus, the necessary and sufficient conditions for the equilibrium of a system of parallel forces in space are that the sum of the projections of all the forces on the coordinate axis parallel to the forces and the sums of the moments of all the forces about the other two coordinate axes must separately vanish.

Fig. 118.

49. Varignon's Theorem of the Moment of a Resultant with Respect to an Axis. Let there be acting on a rigid body a force system F_1, F_2, \dots, F_n which can be reduced to a resultant R whose action line passes through any point C (Fig. 118). Let us apply at the same point a force $R' = -R$. The system F_1, F_2, \dots, F_n, R' will now be in equilibrium and will satisfy all the conditions (66). In particular, for any coordinate axis Ox we shall have:

$$\sum m_x(F_k) + m_x(R') = 0.$$

But as $\mathbf{R}' = -\mathbf{R}$ and both forces are collinear, it follows that $m_x(\mathbf{R}') = -m_x(\mathbf{R})$. Substituting this expression of $m_x(\mathbf{R}')$ in the previous equation, we find that

$$m_x(\mathbf{R}) = \sum m_x(\mathbf{F}_k). \quad (69)$$

Thus, if a given force system has a resultant, the moment of that resultant with respect to any axis is equal to the algebraic sum of the moments of the component forces with respect to the same axis (Varignon's Theorem).

50. Problems on the Equilibrium of Bodies Subjected to the Action of Force Systems in Space. The principle of solving the problems of this section is the same as for coplanar force systems. After isolating the body whose equilibrium has to be considered, the constraints attached to it are replaced by their reactions, the equilibrium equations are written as for a free body, and the required quantities are obtained.

In order to obtain simpler sets of equations, the student is advised to draw the coordinate axes so that they would intersect with, or be perpendicular to, as many unknown forces as possible (if this does not complicate the computation of the projections and moments of other forces).

A new feature in writing equations is the computation of the moments of the forces with respect to the coordinate axes.

If, while examining the general diagram, the student finds difficulty in determining the moment of some force with respect to an axis, he is advised to draw an auxiliary diagram showing the projections of the given body and the required force on a plane normal to the axis under consideration.

If, in computing a moment, there is difficulty in determining the projection of a force on any plane, or the moment arm of the projection, resolve the force into two rectangular components (one of them parallel to a coordinate axis) and then apply Varignon's theorem. The moments can also be computed analytically from Eqs. (52).

Fig. 119.

Problem 43. Three workers lift a homogeneous rectangular plate whose dimensions are a by b (Fig. 119). If one worker is at A , determine the points B and D where the other workers

should stand so that they would all exert the same force.

Solution. The plate is a free body acted upon by four parallel forces Q_1 , Q_2 , Q_3 , and P , where P is the weight of the plate. Assuming that the

plate is horizontal and drawing the coordinate axes as shown in the figure, we obtain from the equilibrium conditions (68):

$$Q_1 b + Q_2 y - P \frac{b}{2} = 0,$$

$$-Q_2 a - Q_3 x + P \frac{a}{2} = 0,$$

$$Q_1 + Q_2 + Q_3 = P.$$

According to the conditions of the problem, $Q_1 = Q_2 = Q_3 = Q$, hence, from the last equation, $P = 3Q$. Substituting this expression in the first two equations and eliminating Q , we have:

$$b + y = \frac{3}{2} b, \quad a + x = \frac{3}{2} a,$$

whence

$$x = \frac{a}{2}, \quad y = \frac{b}{2}.$$

Problem 44. A horizontal shaft supported in bearings A and B as shown has attached at right angles to it a pulley of radius $r_1 = 20$ cm and a drum of radius $r_2 = 15$ cm (Fig. 120). The shaft is driven by a belt passing over the pulley; attached to a cable wound on the drum is a load of weight $P = 180$ kg, which is lifted with uniform motion when the shaft turns. Neglecting the weight of the construction, determine the reactions of the bearings and the tension T_1 in the driving portion of the belt, if it is known that it is double the tension T_2 in the driven portion and if $a = 40$ cm, $b = 60$ cm, and $\alpha = 30^\circ$.

Solution. As the shaft rotates uniformly, the forces acting on it are in equilibrium and the equations of equilibrium can be applied. Drawing the coordinate axes as shown and regarding the shaft as a free body, denote the forces acting on it: the tension F of the cable, which is equal to P in magnitude, the tensions T_1 and T_2 in the belt, and the reactions Y_A , Z_A , Y_B , and Z_B of the bearings (each of the reactions R_A and R_B can have any direction in planes normal to the x axis and they are therefore denoted by their rectangular components).

To write the equilibrium equations (66), calculate the projections of all the forces on, and their moments about, the coordinate axes (see table); as the x projections of all the forces are zero, they have been omitted*.

Fig. 120.

* Tables will be found especially convenient in solving the problems of this chapter. The table is filled column by column, i.e., first the projections and moments of force F are computed, then of force T_1 , etc. In this way attention is focused on every force in succession. If we were to write the equilibrium equations (66) at once, we should have to return to each force six times with a correspondingly greater chance of making a mistake—especially of omitting some force in this or that equation.

F_k	F	T_1	T_2	R_A	R_B
F_{ky}	$F \cos \alpha$	T_1	T_2	Y_A	Y_B
F_{kz}	$-F \sin \alpha$	0	0	Z_A	Z_B
$m_x(F_k)$	$-Fr_2$	$T_1 r_1$	$-T_2 r_1$	0	0
$m_y(F_k)$	$F \sin a \cdot b$	0	0	0	$-Z_B(a+b)$
$m_z(F_k)$	$F \cos a \cdot b$	$-T_1 a$	$-T_2 a$	0	$Y_B(a+b)$

From the equilibrium equations, and noting that $F=P$, we obtain:

$$P \cos \alpha + T_1 + T_2 + Y_A + Y_B = 0, \quad (I)$$

$$-P \sin \alpha + Z_A + Z_B = 0, \quad (II)$$

$$-r_2 P + r_1 T_1 - r_1 T_2 = 0, \quad (III)$$

$$bP \sin \alpha - (a+b) Z_B = 0, \quad (IV)$$

$$bP \cos \alpha - aT_1 - aT_2 + (a+b) Y_B = 0. \quad (V)$$

Remembering that $T_1 = 2T_2$, we find immediately from equations (III) and (IV) that

$$T_2 = \frac{r_2 P}{r_1} = 135 \text{ kg.}$$

$$Z_B = \frac{bP}{a+b} \sin \alpha = 54 \text{ kg.}$$

From equation (V) we obtain

$$Y_B = \frac{3aT_2 - bP \cos \alpha}{a+b} \approx 69 \text{ kg.}$$

Substituting these values in the other equations we find:

$$Y_A = -P \cos \alpha - 3T_2 - Y_B \approx -630 \text{ kg,}$$

$$Z_A = P \sin \alpha - Z_B = 36 \text{ kg,}$$

and finally,

$$T_1 = 270 \text{ kg, } Y_A \approx -630 \text{ kg,}$$

$$Z_A = 36 \text{ kg, } Y_B \approx 69 \text{ kg, } Z_B = 54 \text{ kg.}$$

Problem 45. A rectangular plate of weight $P = 12 \text{ kg}$ making an angle $\alpha = 60^\circ$ with the vertical is supported by a journal bearing at B and a step bearing at A (Fig. 121a).

The plate is kept in equilibrium by the action of a string DE ; acting on the plate is a load $Q = 20 \text{ kg}$ suspended from a string passing over pulley O and attached at K so that KO is parallel to AB . Determine the tension in

Fig. 121a.

string DE and the reactions of the bearings A and B , if $BD = BE$, $AK = a = 0.4$ m, and $AB = b = 1$ m.

Solution. Consider the equilibrium of the plate as a free body. Draw the coordinate axes with the origin at B (in which case force T intersects with the y and z axes, which simplifies the moment equations) and the acting forces and the reactions of the constraints as shown (the dashed vector M belongs to a different problem). For the equilibrium equations, calculate the projections and moments of all the forces; for this we introduce angle β and denote $d = BD = BE$ (see table). Computation of some of the moments is explained in the auxiliary diagrams (Figs 121b and c).

F_k	P	Q'	T	R_A	R_B
F_{kx}	0	$-Q'$	0	X_A	0
F_{ky}	0	0	$-T \sin \beta$	Y_A	Y_B
F_{kz}	$-P$	0	$T \cos \beta$	Z_A	Z_B
$m_x(F_k)$	$-P \frac{d}{2} \sin \alpha$	0	$Td \sin \beta$	0	0
$m_y(F_k)$	$-P \frac{b}{2}$	$Q'a \cos \alpha$	0	$Z_A b$	0
$m_z(F_k)$	0	$Q'a \sin \alpha$	0	$-Y_A b$	0

Fig. 121b shows the projection on plane Byz from the positive end of the x axis. This diagram is useful in computing the moments of forces P and T about the x axis. It can be seen from the diagram that the projections of these forces on the yz plane are equal to the forces, and that the moment arm of force P with respect to point B is $BC_1 \sin \alpha = \frac{d}{2} \sin \alpha$; the moment arm of force T with respect to point B is $BE \sin \beta = d \sin \beta$.

Fig. 121c shows the projection on plane Bxz from the positive end of the y axis. This diagram, together with Fig. 121b, helps to compute the moments of forces P and Q' about the y axis. It can be seen that the projections of these forces on the xz plane are equal to the forces themselves and that

the moment arm of force P with respect to point B is $\frac{1}{2}AB = \frac{b}{2}$; the arm of force Q' with respect to B is AK_1 , i.e., $AK \cos \alpha$, or $a \cos \alpha$, as is evident from Fig. 121b.

Fig. 121b, c.

Writing the equilibrium equations and assuming $Q' = Q$, we obtain:

$$-Q + X_A = 0, \quad (I)$$

$$-T \sin \beta + Y_A + Y_B = 0, \quad (II)$$

$$-P + T \cos \beta + Z_A + Z_B = 0, \quad (III)$$

$$-P \frac{d}{2} \sin \alpha + Td \sin \beta = 0, \quad (IV)$$

$$-P \frac{b}{2} + Qa \cos \alpha + Z_A b = 0, \quad (V)$$

$$Qa \sin \alpha - Y_B b = 0. \quad (VI)$$

Taking into account that $\beta = \frac{\alpha}{2} = 30^\circ$, we find from equations (I), (IV), (V), and (VI) that

$$X_A = Q = 20 \text{ kg}, \quad T = P \frac{\sin \alpha}{2 \sin \beta} \approx 10.4 \text{ kg},$$

$$Z_A = \frac{P}{2} - \frac{Qa}{b} \cos \alpha = 2 \text{ kg}, \quad Y_A = \frac{Qa}{b} \sin \alpha \approx 6.9 \text{ kg}.$$

Substituting these values into equations (II) and (III), we obtain

$$Y_B = T \sin \beta - Y_A = -1.7 \text{ kg}, \quad Z_B = P - T \cos \beta - Z_A = 1 \text{ kg},$$

and finally,

$$T \approx 10.4 \text{ kg}, \quad X_A = 20 \text{ kg}, \quad Y_A \approx 6.9 \text{ kg},$$

$$Z_A = 2 \text{ kg}, \quad Y_B = -1.7 \text{ kg}, \quad Z_B = 1 \text{ kg}.$$

Problem 46. Solve Problem 45 for the case when the plate is additionally subjected to a couple of moment $M = 12 \text{ kg-m}$ acting in the plane of the plate; the sense of rotation (viewed from the top of the plate) is counterclockwise.

Solution. Add to the forces in Fig. 121a the moment vector M of the couple applied at any point perpendicular to the plate, e.g., point A . Its projections are: $M_x = 0$, $M_y = M \cos \alpha$, and $M_z = M \sin \alpha$. Applying the equilibrium equations (67), we find that equations (I) to (IV) remain the same as for Problem 45 while the last two equations will be:

$$-P \frac{b}{2} + Z_A b + Qa \cos \alpha + M \cos \alpha = 0, \quad (V')$$

$$-Y_A b + Qa \sin \alpha + M \sin \alpha = 0. \quad (VI')$$

Note that the same result can be obtained without writing Eqs. (67), by denoting the couple as two forces directed, for example, along AB and KO (their magnitude will, apparently, be M/a) and applying the usual equilibrium equations.

Solving equations (I)-(IV), (V'), and (VI'), we obtain results similar to those in Problem 45, the only difference being that in all the equations Qa will be replaced by $Qa + M$. The answer is:

$$T \approx 10.4 \text{ kg}, \quad X_A = 20 \text{ kg}, \quad Y_A \approx 17.3 \text{ kg}, \quad Z_A = -4 \text{ kg},$$

$$Y_B = -12.1 \text{ kg}, \quad Z_B = 7 \text{ kg}.$$

Problem 47. A horizontal rod AB is attached to a wall by a ball-and-socket joint and is kept perpendicular to the wall by wires KE and CD as shown in Fig. 122a. Hanging from end B is a load of weight $P = 36 \text{ kg}$. Determine the reaction of the ball-and-socket joint and the tensions in the wires if $AB = a =$

$= 0.8$ m, $AC = AD_1 = b = 0.6$ m, $AK = \frac{a}{2}$, $\alpha = 30^\circ$, and $\beta = 60^\circ$. Neglect the weight of the rod.

Solution. Consider the equilibrium of the rod as a free body. Acting on it are force P and reactions T_K , T_C , X_A , Y_A , and Z_A . Draw the coordinate axes and calculate the projections and moments of all the forces. As all the forces pass through the y axis, their moments with respect to it are zero. To compute the moments of force T_C with respect to the coordinate axes, resolve it into components T_1 and T_2 ($T_1 = T_C \cos \alpha$, $T_2 = T_C \sin \alpha$) and apply Varignon's theorem*. We have $m_x(T_C) = m_x(T_1)$, as $m_x(T_2) = 0$, and $m_z(T_C) = m_z(T_2)$,

Fig. 122.

as $m_z(T_1) = 0$. The computation of the moments of the forces with respect to the z axis is explained in the auxiliary diagram 122b showing the projection on plane Axy . The results of the computations are tabulated as follows:

F_k	P	T_K	T_C	R_A
F_{kx}	0	$T_K \cos \beta$	$-T_2 \sin 45^\circ$	X_A
F_{ky}	0	$-T_K \sin \beta$	$-T_2 \cos 45^\circ$	Y_A
F_{kz}	$\perp P$	0	T_1	Z_A
$m_x(F_k)$	$-Pa$	0	$T_1 b$	0
$m_z(F_k)$	0	$-T_K \frac{a}{2} \cos \beta$	$T_2 b \sin 45^\circ$	0

* Attention is drawn to the fact that the angle between force T_C and plane Ayz is not 45° , as is sometimes erroneously assumed in such cases. Therefore, for example, in computing $m_x(T_C)$ in the usual way, it is first necessary to determine the angle, which complicates the computations. With the aid of Varignon's theorem, however, we find immediately that $m_x(T_C) = m_x(T_1) = T_1 AC$.

Substituting the values of T_1 and T_2 we obtain the following equations:

$$T_K \cos \beta - T_C \sin \alpha \sin 45^\circ + X_A = 0, \quad (I)$$

$$-T_K \sin \beta - T_C \sin \alpha \cos 45^\circ + Y_A = 0, \quad (II)$$

$$-P + T_C \cos \alpha + Z_A = 0, \quad (III)$$

$$-Pa + T_C b \cos \alpha = 0, \quad (IV)$$

$$-T_K \frac{a}{2} \cos \beta + T_C b \sin \alpha \sin 45^\circ = 0, \quad (V)$$

solving which we find that $T_C \approx 55.4$ kg, $T_K \approx 58.8$ kg, $X_A \approx -9.8$ kg, $Y_A \approx 70.5$ kg, and $Z_A = -12$ kg. Components X_A and Z_A thus actually act in the opposite direction than that shown in the diagram.

Problem 48. An equilateral triangular plate with sides of length a is supported in a horizontal plane by six bars as shown in Fig. 123. Each inclined bar makes an angle of $\alpha = 30^\circ$ with the horizontal. Acting on the plate is a couple of moment M . Neglecting the weight of the plate, determine the stresses produced in the bars.

Solution. Regarding the plate as a free body, draw, as shown in the figure, the vector of moment M of the couple and the reactions of the bars S_1, S_2, \dots, S_6 . Direct the reactions as if all the bars were in tension (i.e., we assume that the plate is being wrenched off the bars). As the body is in equilibrium, the sums of the moments of all the forces and couples

acting on it with respect to any axis must be zero [see Eqs. (67)].

Drawing axis z along bar 1 and writing the equations of the moment with respect to that axis, we obtain, as $M_z = M$,

$$(S_6 \cos \alpha) h + M = 0,$$

where $h = \frac{a\sqrt{3}}{2}$ is the altitude of the triangle. From this we find:

$$S_6 = -\frac{2\sqrt{3}}{3} \frac{M}{a \cos \alpha}.$$

Writing the equations of the moments with respect to the axes along bars 2 and 3, we obtain similar results for forces S_4 and S_5 .

Now write the equations of the moments about axis x , which is directed along side BA of the triangle. Taking into account that $M_x = 0$, we obtain

$$S_3 h + (S_4 \sin \alpha) h = 0,$$

whence, as $S_4 = S_6$, we find

$$S_3 = -S_4 \sin \alpha = \frac{2\sqrt{3}}{3} \frac{M}{a} \tan \alpha.$$

Writing the moment equations with respect to axes AC and CB , we obtain similar results for S_1 and S_2 .

Finally, for $\alpha = 30^\circ$, we have:

$$S_1 = S_2 = S_3 = \frac{2}{3} \frac{M}{a}; \quad S_4 = S_5 = S_6 = -\frac{4}{3} \frac{M}{a}.$$

Fig. 123.

The answer shows that the given couple creates tensions in the vertical bars and compressions in the inclined ones.

This solution suggests that it is not always necessary to apply equilibrium equations (66). There are several forms of equilibrium equations for non-coplanar force systems, just as for coplanar systems, of which Eqs. (66) are the principal form.

In particular, it can be proved that the necessary and sufficient conditions for the equilibrium of a force system in space are that the sums of the moments of all the forces with respect to each of six axes directed along the edges of any triangular pyramid or along the side and base edges of a triangular prism are each zero.

The latter conditions were applied in solving the above problem.

51. Conditions of Equilibrium of a Constrained Rigid Body. Concept of Stability of Equilibrium. In §§ 11, 24, 48 and others we obtained equations specifying the necessary conditions for the equilibrium of *free rigid bodies*. With regard to constrained bodies, these equations are applied on the basis of the axiom of constraints. The resulting equations define the reactions of the constraints.

The question of the conditions for the equilibrium of a constrained rigid body arises when its supports do not constrain it rigidly (see Problems 6 and 7 in § 13 and others). In this case only some of the equations based on the axiom of constraints contain the reactions of the constraints and can define those reactions. The other equations show the relations between the given forces (Problem 6) or the specific position (Problem 7) in which equilibrium is possible, i.e., they specify the conditions of equilibrium for the given body. Thus, *for the case of a constrained body, the conditions of equilibrium are specified only by those equations based on the axiom of constraints which do not include the reactions of the constraints.*

For instance, applying the axiom of constraints to a body with a fixed axis of rotation (Fig. 124) and writing Eqs. (66), we find that the reactions of bearings A and B are present in all the equations except the last one (see Problem 44). The reactions are absent from equation $\sum m_z(F_k) = 0$ as they intersect with the z axis.

Hence, *the condition for the equilibrium of a body with a fixed axis of rotation is that the sum of the moments of all the acting forces with respect to that axis is zero:*

$$\sum m_z(F_k) = 0. \quad (70)$$

Fig. 124.

For a body whose supports do not constrain it rigidly, the important question of *stability of equilibrium* arises. If the acting forces tend to return a body to its configuration of equilibrium (when it has been displaced from that configuration), the equilibrium is said to be *stable*; otherwise it is *unstable*. In real conditions a body can be in equilibrium only if it is in stable equilibrium.

Consider, for example, a body mounted on a horizontal axis. It will be in equilibrium under the action of the force of gravity P when, according to Eq. (70), $m_z(P) = 0$, i.e., when the centre of gravity C of the body is in its lowest (Fig. 124a) or highest (Fig. 124b) configuration. In the first case, if the body is displaced, the moment of force P tends to return it to its position of equilibrium. In the second case, the slightest displacement of C will cause the moment of P to increase that displacement. Consequently, *equilibrium is stable if the centre of gravity of a body occupies the lowest possible configuration, and unstable when it occupies the highest configuration*. This applies to all cases of equilibrium of bodies in gravity conditions. If the centre of gravity lies on the axis of rotation, the equilibrium is said to be *indifferent* or *neutral*.

Let us consider also the equilibrium of the rod examined in Problem 7 (or in Problem 12). The equilibrium equation for the rod is $\sum m_A(F_k) = 0$. In this case (see Fig 38):

$$m_A(T) = Qa \cos \frac{\alpha}{2}, \quad |m_A(P)| = Pa \sin \alpha.$$

If angle α is increased, $m_A(P)$ increases and $m_A(T)$ decreases, and under the action of force P angle α will continue to increase. If angle α is decreased, $m_A(T)$ increases and $m_A(P)$ decreases, and under the action of force $T = Q$ angle α will continue to decrease. Hence, the equilibrium of the rod as defined by the equation $\sin \frac{\alpha}{2} = \frac{Q}{2P}$ is *unstable*. At $\alpha = 180^\circ$ the equilibrium is stable if $Q < 2P$, and unstable if $Q > 2P$, which can be verified by introducing $\beta = 180^\circ - \alpha$.

This method of analysis is applicable only in the simplest cases. More complex cases are analysed by methods of dynamics.

Chapter 8

CENTRE OF GRAVITY

52. Centre of Parallel Forces. The concept of centre of parallel forces comes in handy when we have to deal with the composition of parallel forces acting on a rigid body whose direction lines change with respect to that body. Specifically, this concept

is useful in solving certain problems of mechanics, in particular, when the centre of gravity of bodies has to be determined.

Consider a system of parallel forces F_1, F_2, \dots, F_n of same sense applied to a rigid body at points A_1, A_2, \dots, A_n (Fig. 125). The resultant R of this system is, evidently, parallel to the component forces in the same direction, and its magnitude is

$$R = \sum F_k. \quad (71)$$

If, now, the given forces are rotated in the same direction through the same angle about their points of application, we obtain new systems of parallel forces of same sense, whose magnitudes and points of application are the same as for the original system, but which act in a different direction (e.g., as shown by the dashed lines in Fig. 125). The resultant of each of these parallel-force systems will, evidently, be of same magnitude R , but differently directed. To determine this direction, we must find for each case a point through which the resultant passes. Let us show that *the action line of a resultant of parallel forces always passes through a certain point C , regardless of the direction of the forces*. Thus, resultant R_1 (not shown in the diagram) of forces F_1 and F_2 will pass through a point c_1 on line A_1A_2 such that $F_1 \cdot A_1c_1 = F_2 \cdot A_2c_2$, regardless of the direction of the forces, since the latter does not affect the location of A_1A_2 or the form of the equation. The resultant of forces R_1 and F_3 (which is the resultant of forces F_1, F_2 , and F_3) will always pass through a point c_2 on line c_1A_3 determined in the same way as point c_1 . By successively compounding all the forces, we find that their resultant R passes through a point C , which is fixed relative to points A_1, A_2, \dots, A_n , and consequently, relative to the body as a whole.

Fig. 125.

The point C , through which the action line of the resultant of a system of parallel forces passes, no matter how those forces are

rotated about their points of application through the same angle in the same direction, is called the *centre of parallel forces*.

Let us find the *coordinates of the centre of parallel forces*. The position of point C with regard to the body is constant and does not depend on the coordinate system. Let us, therefore, take an arbitrary coordinate system $Oxyz$ and denote the coordinates of the points in this system: $A_1(x_1, y_1, z_1)$, $A_2(x_2, y_2, z_2)$, ..., $C(x_C, y_C, z_C)$. As the position of point C does not depend on the direction of the forces, let us first rotate the forces about their points of application to a position parallel to the z axis, and let us apply to the turned forces F'_1, F'_2, \dots, F'_n Varignon's theorem (§ 49). As the resultant of these forces is R' , then, taking the moments of the forces with respect to the y axis, we obtain from Eq. (69):

$$m_y(R') = \sum m_y(F'_k).$$

But from the diagram [or from Eqs. (52)] we see that $m_y(R') = Rx_C$, as $R' = R$; $m_y(F'_1) = F_1x_1$, as $F'_1 = F_1$, etc. Consequently, $Rx_C = F_1x_1 + F_2x_2 + \dots + F_nx_n$, whence

$$x_C = \frac{F_1x_1 + F_2x_2 + \dots + F_nx_n}{R} = \frac{\sum F_kx_k}{R}.$$

We obtain a similar expression for coordinate y_C by taking the moments with respect to the x axis. In order to determine z_C , we again rotate the forces to a position parallel to the y axis (as indicated by dash-dot lines) and apply Varignon's theorem, taking the moments with respect to the x axis. This gives us:

$$-Rz_C = -F_1z_1 + (-F_2z_2) + \dots + (-F_nz_n),$$

whence we find z_C .

We thus obtain the following equations which specify the coordinates of the centre of parallel forces:

$$x_C = \frac{\sum F_kx_k}{R}, \quad y_C = \frac{\sum F_ky_k}{R}, \quad z_C = \frac{\sum F_kz_k}{R}, \quad (72)$$

where R is determined from Eq. (71).

Note that Eqs. (71) and (72) are valid for parallel forces acting in opposite directions, if F_k is taken as an algebraic quantity (i.e., plus for one sense and minus for the opposite sense) and if $R \neq 0$.

53. Centre of Gravity of a Rigid Body. Every particle of a body near the surface of the earth is subjected to the action of a vertical downward force known as the force of gravity. This

force is the resultant of the earth's gravitational force and the centrifugal force generated by the rotation of the earth (this will be discussed in detail in § 121).

For a body that is very small as compared with the earth's radius, the gravity forces acting on its particles may be regarded as parallel to each other and constant in value however the body is turned. A field in which these conditions are satisfied is called a *uniform gravitational field*.

We shall denote the resultant of gravity forces $\mathbf{p}_1, \mathbf{p}_2, \dots, \mathbf{p}_n$ acting on the particles of a given body by the symbol \mathbf{P} (Fig. 126). This force is equal to the weight of the body in magnitude and is specified by the equation*:

$$\mathbf{P} = \sum \mathbf{p}_k. \quad (73)$$

Fig. 126.

The forces \mathbf{p}_k continue to act parallel to each other and are applied at the same points of the body regardless of how it is rotated. It follows, then, as proved in § 52, that the resultant \mathbf{P} of the forces \mathbf{p}_k passes through one, and only one, point C , which is constant for the given body. This point is the centre of the parallel gravity forces \mathbf{p}_k and is called the *centre of gravity* of the body. Thus, *the centre of gravity of a body is a point, constant for every body, through which the resultant of the gravity forces acting on the particles of that body passes, regardless of how the body is orientated in space*. That such a point must always exist follows from the discussion in § 52.

The coordinates of the centre of gravity, as the centre of parallel forces, are specified by Eqs. (72) and are

$$x_C = \frac{\sum p_k x_k}{P}, \quad y_C = \frac{\sum p_k y_k}{P}, \quad z_C = \frac{\sum p_k z_k}{P}, \quad (74)$$

where x_k, y_k, z_k are the coordinates of the points of application of the gravity forces acting on the particles of the body.

* The weight of a body is defined as the force with which a body at rest in a gravitational field acts on a constraint preventing its vertical fall (e.g., the tray of a balance). It will be noted that the familiar feeling of one's own weight is a result of the pressures between the parts of the body produced by the action of gravity forces being opposed by the reactions of the constraints which keep us from falling vertically down. In free vertical fall (e.g., in a lift if the cable breaks) these reciprocal pressures are absent and a person feels "weightless", although the force of gravity continues to act on him. A passenger in an artificial earth satellite will experience a similar sensation.

It should be noted in conclusion that the centre of gravity, by definition, is a geometric point which is not necessarily a part of the body (e.g., the centre of gravity of a ring).

54. Coordinates of Centres of Gravity of Homogeneous Bodies. The weight p_k of any part of a homogeneous body is proportional to the volume of that part, i.e., $p_k = \gamma v_k$; the weight P of the whole body is proportional to its volume V , i.e., $P = \gamma V$, where γ is the weight of a unit volume.

Substituting the values of P and p_k into Eqs. (74), we find that the factor γ appears in both the numerator and the denominator and therefore cancels out. Thus we obtain:

$$x_C = \frac{\sum v_k x_k}{V}, \quad y_C = \frac{\sum v_k y_k}{V}, \quad z_C = \frac{\sum v_k z_k}{V}. \quad (75)$$

We see that the centre of gravity of a homogeneous body depends only on its geometric shape and does not depend on the value of γ . The point C , whose coordinates are specified by Eqs. (75), is called the *centre of gravity of the volume V* .

Reasoning in the same way, we may obtain for a homogeneous lamina the equations

$$x_C = \frac{\sum s_k x_k}{S}, \quad y_C = \frac{\sum s_k y_k}{S}, \quad (76)$$

where S is the area of the lamina and s_k the areas of its divisions.

The point whose coordinates are specified by Eqs. (76) is called the *centre of gravity of the area S* .

The equations specifying the coordinates of the *centre of gravity of a line* are deduced similarly:

$$x_C = \frac{\sum l_k x_k}{L}, \quad y_C = \frac{\sum l_k y_k}{L}, \quad z_C = \frac{\sum l_k z_k}{L}. \quad (77)$$

where L is the length of the line and l_k the lengths of its divisions.

Eqs. (77) are convenient for determining the centre of gravity of articles made of thin wire of uniform cross section.

Thus, the centre of gravity of a homogeneous body is determined as the centre of gravity of the respective volume, area or line. (The centre of gravity of a geometrical figure—a volume, area or line—is often referred to as its centroid, since, strictly speaking, a geometrical figure has no weight.)

55. Methods of Determining the Coordinates of the Centre of Gravity of Bodies. Proceeding from the general formulas evolved above, the following methods are suggested for determining the coordinates of the centre of gravity of various bodies:

1) **Method of Symmetry.** Let us prove that if a body has a plane, axis, or centre of symmetry, its centre of gravity is coincident with the plane, axis or centre, respectively.

Consider a homogeneous body which has a plane of symmetry. This plane, then, divides the body into two parts of equal weight p_1 and p_2 , the centres of gravity of which lie at equal distances from the plane of symmetry. Consequently, the centre of gravity of the body, as a point through which the resultant of the two equal and parallel forces p_1 and p_2 passes, must lie in the plane of symmetry. The proof is similar for the case of bodies with an axis or centre of symmetry.

It follows, by virtue of the properties of symmetry, that the centre of gravity of a homogeneous ring, disc, rectangular lamina, rectangular parallelepiped, sphere, and other homogeneous bodies having a centre of symmetry, is coincident with their geometric centre (centre of symmetry).

2) **Method of Division.** If a body can be divided into a finite number of elements, for each of which the centre of gravity is known, the coordinates of the centre of gravity of the body as a whole can be directly calculated from Eqs. (74)-(77). The number of components in the numerators will be equal to the number of elements into which the body is divided.

Problem 49. Locate the centre of gravity of the homogeneous thin plate shown in Fig. 127 (the dimensions are given in centimetres).

Solution. After choosing the coordinate axes and dividing the plate into three rectangles as shown, we compute the coordinates of the centre of gravity and the area of each rectangle:

Nos.	1	2	3
x_k	-1	1	5
y_k	1	5	9
s_k	4	20	12

The total area of the plate is

$$S = s_1 + s_2 + s_3 = 36 \text{ cm}^2.$$

Fig. 127.

Substituting the computed values in Eqs. (76), we have:

$$x_C = \frac{x_1 s_1 + x_2 s_2 + x_3 s_3}{S} = \frac{-4 + 20 + 60}{36} = 2 \frac{1}{9} \text{ cm.}$$

$$y_C = \frac{y_1 s_1 + y_2 s_2 + y_3 s_3}{S} = \frac{4 + 100 + 108}{36} = 5 \frac{8}{9} \text{ cm.}$$

The location of the centre of gravity C is shown in the diagram, and in this case it is outside of the plate. This example shows again that the centre of gravity of a body is a geometric point which is not necessarily a part of the body.

3) **Method of Supplementation.** This method is a special case of the method of division and it is used to locate the centres of gravity of bodies with holes or cavities, if the centres of the body as a whole without the cavity, and of the cavity itself, are known.

Problem 50. Determine the centre of gravity of a thin disc of radius R with a circle of radius r cut out of it (Fig. 128). The distance $C_1C_2 = a$.

Solution. The centre of gravity of the disc lies on the line C_1C_2 , as it is the axis of symmetry. Draw the coordinate axes as shown. To find the coordinate x_C , first supplement the missing part of the plate to make a uniform disc and then reduce the whole by the area of the cut-out circle, taking that area with a negative sign. We have: $s_1 = \pi R^2$, $x_1 = 0$, $s_2 = -\pi r^2$, $x_2 = a$, $S = s_1 + s_2 = \pi(R^2 - r^2)$.

Substituting these values into Eqs. (76), we obtain:

$$x_C = \frac{x_1 s_1 + x_2 s_2}{S} = -\frac{ar^2}{R^2 - r^2}; y_C = 0.$$

The centre of gravity, we find, lies to the left of C_1 .

4) **Method of Integration.** If a body cannot be divided into a finite number of elements with known centres of gravity, it is first divided into infinitesimal elements of volume Δv_k , for which Eqs. (75) acquire the form

$$x_C = \frac{\sum x_k \Delta v_k}{V}, \text{ etc.}, \quad (78)$$

where x_k, y_k, z_k are the coordinates of a point inside the volume Δv_k . Passing to the limit in Eqs. (78), with $\Delta v_k \rightarrow 0$, i.e., reducing the elementary volumes to points, we replace the summations in the numerators by integrals over the volume of the body. In the limit, Eqs. (78) give

$$x_C = \frac{1}{V} \int_V x dv, \quad y_C = \frac{1}{V} \int_V y dv, \quad z_C = \frac{1}{V} \int_V z dv. \quad (79)$$

Fig. 128.

Similarly, for the coordinates of the centre of gravity of an area or curve we obtain in the limit, from Eqs. (76) and (77),

$$x_c = \frac{1}{S} \int_{(S)} x ds, \quad y_c = \frac{1}{S} \int_{(S)} y ds \quad (80)$$

and
$$x_c = \frac{1}{L} \int_{(L)} x dl, \quad y_c = \frac{1}{L} \int_{(L)} y dl, \quad z_c = \frac{1}{L} \int_{(L)} z dl. \quad (81)$$

An example of the use of the method of integration is given in the following section.

5) Experimental Method. The centre of gravity of a composite non-homogeneous body, say an aircraft or locomotive, can be determined experimentally. In one method (the method of suspension), the body is suspended by strings or ropes attached to different points. The direction of the string supporting the body will each time give the direction of the gravitational force. The point of intersection of these directions locates the centre of gravity of the body.

Another method of experimentally locating the centre of gravity is the method of weighing, explained by the following example.

Example. Determine the centre of gravity of an aircraft (the distance a in Fig. 129) if distance $AB = l$ is known.

By placing wheel B on the platform of a balance, we determine the pressure exerted by the wheel, and hence the reaction N_1 . Similarly, we determine the reaction N_2 . Equating to zero the sums of the moments of all the forces with respect to the centre of gravity C , we obtain $N_2 a - N_1 (l - a) = 0$, whence

$$a = \frac{N_1 l}{N_1 + N_2}.$$

Obviously $N_1 + N_2 = P$, where P is the weight of the aircraft. If P is immediately known, a single weighing is sufficient.

Fig. 129.

Fig. 130.

56. Centre of Gravity of Some Homogeneous Bodies.

1) Centre of Gravity of a Circular Arc. Consider an arc AB of radius R subtending a central angle $AOB = 2\alpha$ (Fig. 130). By virtue of its symmetry, the centre of gravity of the arc lies on the x axis. Let us determine the coordinate x_c by integration (an alternate method, without integration, is given below). For this take an element MM' of length $dl = R d\varphi$ on the arc. Its loca-

tion is defined by angle φ . The x coordinate of the element MM' is $x = R \cos \varphi$. Substituting these values of x and dl in the first of Eqs. (81), and remembering that the integral must be over the whole length of the arc, we obtain:

$$x_C = \frac{1}{L} \int_A^B x dl = \frac{R^2}{L} \int_{-\alpha}^{\alpha} \cos \varphi d\varphi = 2 \frac{R^2}{L} \sin \alpha,$$

where L is the length of the arc AB , which is equal to $R2\alpha$. Hence, the centre of gravity of a circular arc lies on its axis of symmetry at a distance from the centre

$$x_C = R \frac{\sin \alpha}{\alpha}, \quad (82)$$

where angle α is measured in radians.

The same result can be obtained without direct integration. If we denote the length of an arc element by the symbol Δl_k , Eq. (77) gives

$$x_C = \frac{1}{L} \sum x_k \Delta l_k,$$

where x_k is the coordinate of element Δl_k with an accuracy to infinitesimals of higher order, we have $x_k = R \cos \varphi_k$ (substituting φ_k for φ). Then (see Fig. 75, § 28), $x_k \Delta l_k = R \Delta l_k \cos \varphi_k = R \Delta y_k$, whence $\sum x_k \Delta l_k = R \sum \Delta y_k = R \cdot AB$. And finally, noting that $AB = 2R \sin \alpha$ and $L = R \cdot 2\alpha$, we arrive at Eq. (82).

2) Centre of Gravity of a Triangular Area. Let us divide triangle ABD (Fig. 131) into n narrow strips parallel to side AD . The centres of gravity of these strips will, evidently, lie on median BE of the triangle. We conclude, then, that the centre of gravity of the triangle lies on this median. A similar result is obtained for the other two medians. We conclude therefore that the centre of gravity of a triangular area lies at the intersection of its medians. And, as is known,

$$CE = \frac{1}{3} BE.$$

3) Centre of Gravity of a Circular Sector. Consider a circular sector OAB of radius R whose central angle is 2α (Fig. 132). Let us divide the area of the sector with radii

Fig. 131.

Fig. 132.

drawn from O into n sectors. In the limit, when we increase n indefinitely, we can regard the sectors as triangular areas the centres of gravity of which lie on arc DE of radius $\frac{2}{3}R$. Consequently, the centre of gravity of the sector OAB is coincident with the centre of gravity of arc DE , the location of which is determined by Eq. (82). Thus, *the centre of gravity of a circular sector lies on its axis of symmetry at a distance from its centre*

$$x_c = \frac{2}{3}R \frac{\sin \alpha}{\alpha}. \quad (83)$$

4) **Centre of Gravity of a Pyramid.** Consider the triangular pyramid (tetrahedron) $ABDE$ in Fig. 133. To locate its centre of gravity, let us divide it with planes parallel to base ABD into n infinitesimal truncated pyramids, which can be regarded in the limit, when n is increased indefinitely, as plane triangles. The centres of gravity of these triangles lie on line EC_1 joining the vertex E of the pyramid and the centre of gravity C_1 of its base. Consequently, the centre of gravity of the pyramid lies on line EC_1 .

Reasoning in the same way, we find that the centre of gravity also lies on line BC_2 joining vertex B with the centre of gravity of base ADE . Hence, the required centre of gravity lies at point C where EC_1 and BC_2 intersect.

Let us now locate point C . As C_1C_2 and BE divide the sides of angle BKE into proportional segments, they are parallel, and triangle C_1CC_2 is similar to triangle ECB . Furthermore, $C_1C_2 = \frac{1}{3}BE$, as $KC_1 = \frac{1}{3}KB$. We thus find:

$$\frac{CC_1}{CE} = \frac{C_1C_2}{BE} = \frac{1}{3},$$

whence

$$CC_1 = \frac{1}{3}CE = \frac{1}{4}C_1E. \quad (84)$$

This formula is valid for any polyhedral pyramid and, in the limit, for a cone.

Thus, *the centre of gravity of a pyramid (or cone) lies on the line joining the vertex of the pyramid (cone) and the centre of gravity of the base, at a distance from the base equal to one quarter of the length of the whole line.*

Formulas for the coordinates of the centres of gravity of other homogeneous bodies can be found in various technical and mathematical handbooks.

Fig. 133.

PART II

KINEMATICS OF A PARTICLE AND A RIGID BODY

Chapter 9

RECTILINEAR MOTION OF A PARTICLE

57. Introduction to Kinematics. *Kinematics* is that division of mechanics which treats of the geometry of the motion of bodies, without taking into account their inertia (mass) or the forces acting on them.

On the one hand, kinematics is an introduction to dynamics, insofar as the fundamental concepts and relationships of kinematics have to be understood before studying the motion of bodies taking into account the action of forces. On the other hand, the methods of kinematics are in themselves of practical importance, for example in studying the transmission of motion in mechanisms. That is why the demands of the developing machine-building industry led to the emergence of kinematics as a separate division of mechanics (in the first half of the 19th century).

By *motion* in mechanics is meant the relative displacement with time of a body in space with respect to other bodies.

In order to locate a moving body (or particle) we assume a coordinate system, which we call the *frame of reference* or reference system, to be fixed relative to the body with respect to which the motion is being considered. If the coordinates of all the points of a body remain constant within a given frame of reference, the body is said to be at *rest* relative to that reference system. If, on the other hand, the coordinates of any points of the body change with time, the body is said to be in motion relative to the given frame of reference (and consequently, relative to a body which is fixed with respect to the frame of reference). When we speak of the motion of a body with respect to a given frame of reference, we shall mean its motion relative to a body fixed with respect to that frame of reference.

Any motion in space takes place with time. In mechanics we deal with three-dimensional Euclidean space in which all dimensions are measured by the methods of Euclidean geometry. The unit of length, by which distance is measured, is the metre. Time in mechanics is considered as universal, i.e., as passing simultaneously in all our frames of reference. The unit of time is one second, which constitutes $\frac{1}{24 \cdot 3,600} = \frac{1}{86,400}$ th of the mean solar day.

Euclidean space and universal time reflect only approximately the actual properties of space and time. Our daily experience shows, however, that for the motions considered in mechanics (at velocities much below the velocity of light) the approximation is sufficiently accurate for all practical purposes.

Time is a continuously varying scalar quantity. In problems of kinematics, time t is taken as an independent variable (the argument). All other variables are regarded as changing with time, i.e., as functions of time t . Time is measured from some *initial instant* ($t=0$) which is specified for every problem. Any given *instant of time* t is specified by the number of seconds that has passed between the initial and the given time. The difference between successive instants of time is called the *time interval*.

The principles of kinematics, evolved from and confirmed by practical experience, are based on the axioms of geometry. No other laws or axioms are necessary for the kinematic study of motion.

For the solution of problems of kinematics, the specific motion under consideration has to be described. *To describe the motion, or the law of motion, of a given body (particle) kinematically means to specify the position of that body (particle) relative to a given frame of reference for any moment of time. One of the main problems of kinematics is that of describing the motion of particles or bodies in terms of mathematical expressions.*

The *principal problem of kinematics* is that of determining all the kinematic characteristics of the motion of a body as a whole or of any of its particles (path, velocity, acceleration, etc.) when the law of motion for the given body is known.

For the solution of this problem we must know either the equations of motion for the given body or for another body kinematically associated with it.

We shall start the study of kinematics with an investigation of the motion of the simplest body—a particle (kinematics of a particle), proceeding later to the examination of the kinematics of rigid bodies.

The continuous curve described by a particle moving with respect to a given frame of reference is called the *path* of that particle. If the path is a straight line the motion is said to be *rectilinear*, if the path is a curve the motion is *curvilinear*. In this chapter we shall consider the case of rectilinear motion of a particle.

58. Equation of Rectilinear Motion. Consider a particle M moving in a straight line. If we take a point O on that line as the origin of a coordinate system and direct axis Ox along the

line (Fig. 134), the position of the particle on the axis will be specified by its x coordinate, equal to the distance OM taken with the appropriate sign. The displacement of particle M carries it through positions M_1 , M_2 , etc., i.e., the value of x changes continuously. The position of the particle on its path at any given instant is specified by the relationship

$$x = f(t). \quad (1)$$

Fig. 134.

Eq. (1) is the *general expression of rectilinear motion of a particle*.

For example, if the displacement of a particle moving from the origin O is proportional to the square of time, the motion of that particle is given by the equation

$$x = at^2,$$

where a is a factor equal to the distance travelled by the particle in the first second. At time $t_2 = 2$ sec, the particle will be at a distance $4a$ from the origin. Thus, if we know Eq. (1), we can determine the position of a moving particle for any moment of time.

It should be noted that the quantity x in Eq. (1) specifies the *position* of a moving particle, *not the distance travelled* by it. Thus, if a particle moving from O reaches position M_1 (see Fig. 134) and then reverses its motion and returns to M , its coordinate by that time will be $x = OM$, but the distance travelled by it will be $OM_1 + M_1M$, i.e., not equal to x .

§ 59. Velocity and Acceleration of a Particle in Rectilinear Motion. One of the basic kinematic characteristics of a moving particle is its velocity. An important concept is that of average velocity.

If the position of a particle at time t is M , and at time t_1 it becomes M_1 , its displacement in the time interval $\Delta t = t_1 - t$ being $\Delta x = x_1 - x$ (Fig. 135), the average velocity of the particle will be a vector quantity the numerical value* of which is

$$v_{av} = \frac{x_1 - x}{t_1 - t} = \frac{\Delta x}{\Delta t}. \quad (2)$$

* The numerical (or algebraic) value of any vector u can differ from its modulus only in sign. Accordingly, we shall denote the numerical value of a vector by the same symbol u that we use to denote its modulus. In practice this notation will not lead to any misunderstandings. Whenever it is important to stress the fact that the quantity under consideration is the modulus of a vector u , we shall employ the symbol $|u|$.

The vector of average velocity v_{av} has the same direction as the displacement of the particle, i.e., from M to M_1 .

The less the interval of time $\Delta t = t_1 - t$ for which the average velocity is computed, the more accurately will the quantity v_{av} characterise the motion of the particle. In order to obtain a characteristic of motion which would be independent of the time interval Δt , the concept of *instantaneous velocity* of a particle at a given time is introduced.

The instantaneous velocity of a particle at a time t is the quantity v towards which the average velocity v_{av} tends when the time interval Δt tends to zero. The numerical value of v is

$$v = \lim_{\Delta t \rightarrow 0} \frac{\Delta x}{\Delta t} \quad \text{or} \quad v = \frac{dx}{dt}. \quad (3)$$

Fig. 135.

Thus, in rectilinear motion the numerical value of the instantaneous velocity of a particle is equal to the first derivative of its coordinate x with respect to time t .

The velocity v can have a positive or negative value. It is evident from Eq. (3) that the sign of v is the same as the sign of Δx ; consequently, if $v > 0$ the motion of the particle is in the direction of x increasing (the vector v is in the positive direction of the x axis); if $v < 0$ the motion is in the direction of x decreasing (the vector v is in the negative direction of the x axis). The dimension of velocity is length time, specifically m/sec.

The velocity of a particle may change in the course of its motion. The quantity characterising the time rate of change of velocity of a particle is called the *acceleration of that particle*.

Let us first introduce the concept of average acceleration. If the velocity of a particle at any time t is v , and at time t_1 it has become v_1 , i.e., receives an increment $\Delta v = v_1 - v$, the average acceleration of the particle in the time interval $\Delta t = t_1 - t$ is a vector quantity w_{av} , the numerical value of which is determined by the equation

$$w_{av} = \frac{v_1 - v}{t_1 - t} = \frac{\Delta v}{\Delta t}. \quad (4)$$

The vector w_{av} is in the positive direction of the axis when $w_{av} > 0$, and in the negative direction when $w_{av} < 0$.

The instantaneous acceleration of a particle for any given time t is defined as the limit towards which the average acceleration w_{av} tends when the time interval Δt tends to zero; its numerical value is

$$w = \lim_{\Delta t \rightarrow 0} \frac{\Delta v}{\Delta t} = \frac{dv}{dt},$$

or, taking into account Eq. (3),

$$w = \frac{dv}{dt} = \frac{d^2x}{dt^2}. \quad (5)$$

Thus, in rectilinear motion the numerical value of the instantaneous acceleration of a particle is equal to the first derivative of the velocity, or the second derivative of the coordinate x of the particle with respect to time.

The vector of acceleration w is in the positive direction of the x axis when $w > 0$, and in the negative direction when $w < 0$.

Fig. 136.

The dimension of acceleration is length/time², specifically m/sec².

If the velocity of a moving particle increases, the motion is said to be *accelerated*, if the velocity decreases, the motion is said to be *retarded*, or *decelerated*. Evidently, the rectilinear

motion of a particle is accelerated when the velocity and acceleration vectors are in the same direction, i.e., when v and w have the same signs (Fig. 136a); it is retarded when the velocity and acceleration vectors are of opposite sense, i.e., when v and w have opposite signs (Fig. 136b).

The obtained formulas show that if we know the equation of motion of a particle in the form (1), we can determine not only the position of the particle at any instant but also the basic characteristics of its motion, i.e., velocity and acceleration.

60. Some Examples of Rectilinear Motion of a Particle. The motion of a particle along its path, in particular in a straight line, may be described by different equations. Let us examine some of them.

1) **Uniform Motion.** *Uniform rectilinear motion* is defined as rectilinear translation with constant velocity ($v = \text{const.}$). The equation of such motion has the form*:

$$x = x_0 + vt, \quad (6)$$

where x_0 is the coordinate of the particle at time $t = 0$.

It is apparent that the displacement s of the particle in the time t is $x - x_0$. It follows, then, that in uniform motion the displacement of a particle is proportional to time,

* Eqs. (6) and (8) can also be derived in the same way as for curvilinear motion in § 70.

and the velocity is equal to the ratio of the distance to time:

$$s = vt; \quad v = \frac{s}{t}. \quad (7)$$

As the velocity v is constant, the acceleration in this type of motion is zero ($\omega = 0$).

2) **Uniformly Variable Motion.** *Uniformly variable rectilinear motion* is defined as rectilinear translation with constant acceleration ($\omega = \text{const.}$). The equation of such motion has the form:

$$x = x_0 + v_0 t + \frac{1}{2} \omega t^2, \quad (8)$$

where v_0 is the initial velocity of the particle (the velocity at time $t = 0$).

Differentiating Eq. (8) with respect to time, we find that the velocity of uniformly variable motion at any instant is

$$v = v_0 + \omega t. \quad (9)$$

Thus, the velocity of this type of motion increases in proportion to time (i.e., uniformly) and the displacement (at $v_0 = 0$) is proportional to the square of the time.

If v and ω are of the same sign the motion is *uniformly accelerated*, if they are of opposite sign the motion is *uniformly retarded*.

An example of uniformly variable rectilinear motion is the motion of a weight thrown vertically up or down (neglecting the resistance of the atmosphere).

3) **Harmonic Motion.** Consider the rectilinear motion of a particle, the distance x of which from the origin O of a coordinate system changes according to the equation

$$x = a \cos kt, \quad (10)$$

where a and k are constants.

In the motion defined by this equation, a particle M (Fig. 137) oscillates between positions $M_0 (+a)$ and $M_1 (-a)$. Motion of this type, which is known as *simple harmonic motion*, plays an important part in engineering. The quantity a , which is the greatest displacement of the particle from the centre O , is called the *amplitude of vibration*.

It will be noticed that if motion starts at time $t = 0$ from point M_0 , the particle will return to that point at a time t_1 , for which $\cos kt_1 = 1$, or $kt_1 = 2\pi$.

Fig. 137.

The time $T = t_1 = \frac{2\pi}{k}$ required for the point to make one complete cycle is called the *period of vibration*.

Differentiating x with respect to t , we obtain the numerical values of the velocity and acceleration of the particle:

$$v = -ak \sin kt, \quad w = -ak^2 \cos kt.$$

Thus, in this type of motion the velocity and acceleration of a particle change with time according to the law of harmonic motion. When the particle is at the centre of vibration ($x=0$ and $\cos kt=0$), its acceleration $w=0$ and its velocity has a maximum value $v_{\max}=ak$ (at $\cos kt=0$, $\sin kt=\pm 1$); in the extreme positions M_0 and M_1 , where $x=\pm a$ and $\cos kt=\pm 1$, the velocity is zero and the acceleration has a maximum value $w_{\max}=ak^2$.

The signs of v and w show that when the particle moves towards the centre of vibration its motion is accelerated, when it moves away from the centre of vibration it is retarded.

Motion of a similar type is described by the equation $x=a \sin kt$, only the motion starts at the centre O .

61. Graphs of Displacement, Velocity and Acceleration of a Particle. If we lay off the time t to scale on the axis of abscissas, and the displacement x on the ordinate axis, the plotted curve $x=f(t)$ gives us a *displacement-time graph* for a given particle. It shows graphically the displacement of the particle (the change of its x coordinate) with reference to time.

Similarly, we can plot curves to some scale to represent the *velocity-time* relationship $v(t)$ and the *acceleration-time* relationship $w(t)$ for a moving particle.

In Figs 138 *a*, *b*, and *c* are given graphs for the cases of motion described by Eqs. (6), (8), and (10): the displacement-time graphs (top row), the velocity-time graphs (middle row), and the acceleration-time graphs (bottom row).

The displacement-time curve of uniform motion, we see, is a straight line inclined to the axis of abscissas, the velocity-time curve of such motion is a straight line parallel to the axis of abscissas ($v=\text{const.}$), and the acceleration-time curve is a straight line coincident with the axis of abscissas ($w=0$). For uniformly variable motion (accelerated in the case shown in Fig. 138 *b*), the displacement curve is a branch of a parabola, the velocity curve is a straight line inclined to the axis of abscissas, and the acceleration curve is a straight line parallel to the axis of abscissas ($w=\text{const.}$). Finally, for simple harmonic motion

Fig. 138.

(Fig. 138 *c*) the respective graphs are represented by cosine and sine curves.

A displacement graph for a particle should not be confused with its path, which in all the above cases is a straight line.

62. Solution of Problems. Problems solvable by the methods of particle kinematics may require the determination of the velocity or acceleration (and, in curvilinear motion, also the path) of a particle, the time in which a given displacement has been carried out, the distance travelled in a given time, etc.

Before solving any such problem, it is necessary to *establish the law of motion of the given particle*. Either of two cases is possible:

1) The law of motion is given by an equation of motion or by stating the type of motion (e.g., "a particle moves uniformly...", "a uniformly retarded particle..."). In such cases the solution is reduced to the application of the relevant formulas.

2) The law of motion is not given, but the motion of a particle depends in some way on the given motion of another particle (or body). In this case *the solution must start with the deduction of the equations of motion for the given particle*.

Problem 51. A train travelling at a velocity $v_0 = 54$ km/h stops in $t_1 = 2$ min after braking starts. Assuming the motion of the train during braking to be uniformly retarded, determine the distance covered during the braking time.

Solution. The problem states that the motion is uniformly retarded. Consequently, it is described by Eq. (8):

$$x = v_0 t + \omega \frac{t^2}{2}, \quad (a)$$

where x is measured from the place where braking began (therefore $x_0 = 0$). The velocity is

$$v = v_0 + \omega t. \quad (b)$$

As the train stops at $t = t_1$, its velocity at that instant is $v_1 = 0$. Substituting these values in equation (b), we obtain $0 = v_0 + \omega t_1$, whence we find the acceleration:

$$\omega = -\frac{v_0}{t_1}.$$

Substituting the value of ω into equation (a) and assuming $t = t_1$, we obtain the required distance:

$$x_1 = \frac{v_0 t_1}{2} = 900 \text{ m.}$$

It should be noted that in the numerical computations special attention should be paid to expressing all quantities in the same unit systems (distance is usually measured in metres and time in seconds). In our case,

$$v_0 = \frac{54 \cdot 1,000}{3,600} = \frac{54}{3.6} = 15 \text{ m/sec; } t_1 = 120 \text{ sec.}$$

Fig. 139.

Problem 52. A man of height h walks away from a lamp hanging at a height H with a velocity u . Determine the velocity of the tip of the man's shadow.

Solution. First let us establish the law of motion of the tip of the shadow. Choosing point O directly under the lamp as the origin of our frame of reference, draw the x axis to the right, as shown in Fig. 139. Now, depicting the man at an arbitrary distance x_1 from O , we find that the tip of his shadow is at x_2 .

By virtue of the similarity of triangles OAM and DAB , we have:

$$x_2 = \frac{H}{H-h} x_1.$$

This is the equation of motion for the tip of the shadow M , provided the equation of motion for the man, i.e., $x_1 = f(t)$, is known.

Differentiating both parts of the equation with respect to time and noting that $\frac{dx_1}{dt} = u$ and $\frac{dx_2}{dt} = v$, where v is the required velocity, we obtain:

$$v = \frac{H}{H-h} u.$$

If the man moves with uniform velocity ($u = \text{const.}$), the velocity of the shadow v is also uniform, but it is $\frac{H}{H-h}$ times faster than that of the man.

It should be noted that in developing the equations of motion, the moving body or mechanism (see Problem 53) should be drawn in an arbitrary position. Only

thus can we obtain an equation specifying the position of a moving particle (or body) at any moment of time.

Problem 53. Blocks A and B of the mechanism in Fig. 140 are connected by a rod AB of length $l = 30$ cm and move in mutually perpendicular directions when the crank rotates. The crank OD of length $\frac{l}{2}$ is hinged to the middle of the rod AB at D . Develop the equations of motion for the sliding blocks A and B if angle φ increases in proportion to time (such rotation is called uniform) and the speed of rotation of the crank is 2 rpm. Determine the velocity and acceleration of the blocks at the instant when angle $\varphi = 30^\circ$.

Solution. The equations of motion for points A and B can be developed from the equation of motion for the crank OD . According to the conditions of the problem, $\varphi = kt$, where k is a constant factor. We also know that, at $t = 60$ sec, angle $\varphi = 4\pi$ (two revolutions). Hence, $4\pi = 60k$, and $k = \pi/15$.

Now we can draw the coordinate axes Ox and Oy and evolve the equations of motion for the blocks. As $OD = AD$, $\angle OAB = \varphi$. Hence, $x_A = l \cos \varphi$, and $y_B = l \sin \varphi$, or

$$x_A = l \cos kt; \quad y_B = l \sin kt. \quad (a)$$

The equations show that both blocks are in simple harmonic motion. Differentiating x_A and y_B with respect to time, we obtain the velocity and acceleration of the blocks:

$$\begin{aligned} v_A &= -kl \sin kt, & w_A &= -k^2 l \cos kt; \\ v_B &= kl \cos kt, & w_B &= -k^2 l \sin kt. \end{aligned}$$

When angle $\varphi = 30^\circ$, $kt = \frac{\pi}{6}$. At that instant

$$v_A = -\frac{kl}{2} = -3.14 \text{ cm/sec}, \quad w_A = -\frac{k^2 l \sqrt{3}}{2} = -1.14 \text{ cm/sec}^2,$$

$$v_B = \frac{kl \sqrt{3}}{2} = 5.44 \text{ cm/sec}, \quad w_B = -\frac{k^2 l}{2} = -0.66 \text{ cm/sec}^2.$$

The signs indicate the directions of the velocity and acceleration vectors. In the case examined above, block A is moving with acceleration and block B with retardation.

Fig. 140.

Chapter 10

CURVILINEAR MOTION OF A PARTICLE

63. Vector Method of Describing Motion of a Particle. To describe the motion of a particle, it is necessary to specify its position in a chosen frame of reference at any given moment of time. Curvilinear motion can be described by one of the following three methods: 1) the vector method, 2) the coordinate method, 3) the natural method.

We shall start with the *vector method* of describing motion. Let a particle M be moving relative to any frame of reference $Oxyz$. The position of the particle at any instant can be specified by a vector \mathbf{r} drawn from the origin O to the particle M (Fig. 141).

Fig. 141.

Vector \mathbf{r} is called the *radius vector* of the particle M .

When the particle moves, the vector changes with time both in magnitude and direction. Thus, \mathbf{r} is a variable vector (a vector-function) depending on the argument t :

$$\mathbf{r} = \mathbf{r}(t). \quad (11)$$

Eq. (11) describes the curvilinear motion of a particle in vector form, insofar as it makes it possible to construct a vector \mathbf{r} for any particular moment of time and to determine the position of the moving particle at that moment*.

The locus of the tip of vector \mathbf{r} defines the path of the moving particle.

64. Velocity Vector of a Particle. Let a moving particle occupy at time t a position M defined by the radius vector \mathbf{r} , and

at time t_1 a position M_1 defined by the radius vector \mathbf{r}_1 (Fig. 142). The displacement during the time interval $\Delta t = t_1 - t$ is defined by a vector $\overline{MM_1}$, which we shall call the *displacement vector* of the particle.

From triangle OMM_1 , we have $\mathbf{r} + \overline{MM_1} = \mathbf{r}_1$, whence

$$\overline{MM_1} = \mathbf{r}_1 - \mathbf{r} = \Delta \mathbf{r}.$$

The ratio of the displacement vector of a particle to the corresponding time interval defines the vector of average

(both in magnitude and direction) velocity of the particle during the given time interval:

$$\mathbf{v}_{av} = \frac{\overline{MM_1}}{\Delta t} = \frac{\Delta \mathbf{r}}{\Delta t}. \quad (12)$$

* Vector \mathbf{r} can be defined by its magnitude and the angles it makes with the coordinate axes or by its projections on the axes. Thus, Eq. (11) stands for a set of equations giving the dependence of r , α , β , and γ on t , or of r_x , r_y , and r_z on t .

The magnitude of the average velocity given by Eq. (12) is

$$v_{av} = \frac{MM_1}{\Delta t}. \quad (12')$$

Vector \mathbf{v}_{av} has the same direction as vector $\overline{MM_1}$, i.e., along the chord MM_1 , in the direction of the motion of the particle (the direction of the vector is not altered by being divided by Δt).

The instantaneous velocity of a particle at any time t is defined as the vector quantity \mathbf{v} towards which the average velocity \mathbf{v}_{av} tends when the time interval Δt tends to zero:

$$\mathbf{v} = \lim_{\Delta t \rightarrow 0} (\mathbf{v}_{av}) = \lim_{\Delta t \rightarrow 0} \frac{\Delta \mathbf{r}}{\Delta t}.$$

The limit of the ratio $\frac{\Delta \mathbf{r}}{\Delta t}$ when $\Delta t \rightarrow 0$ is the first derivative of the vector \mathbf{r} with respect to t and is denoted, like the derivative of a scalar function, by the symbol $\frac{d\mathbf{r}}{dt}$ *.

Finally we obtain:

$$\mathbf{v} = \frac{d\mathbf{r}}{dt}. \quad (13)$$

Thus, the vector of instantaneous velocity of a particle is equal to the first derivative of the radius vector of the particle with respect to time.

As the limiting direction of the secant MM_1 is a tangent, the vector of instantaneous velocity is tangent to the path of the particle in the direction of motion.

Eq. (13) also shows that the velocity vector \mathbf{v} is equal to the ratio of the infinitesimal displacement $d\mathbf{r}$ of the particle tangent to its path to the corresponding time interval dt .

65. Acceleration Vector of a Particle. In curvilinear motion, acceleration characterises the time rate of change of velocity in magnitude and direction.

Let a moving particle occupy a position M and have a velocity \mathbf{v} at a given time t , and let it at time t_1 occupy a position M_1 and have a velocity \mathbf{v}_1 (Fig. 143). The increase in velocity in the time interval $\Delta t = t_1 - t$ is $\Delta \mathbf{v} = \mathbf{v}_1 - \mathbf{v}$. To construct vector $\Delta \mathbf{v}$, lay off vector \mathbf{v}_1 from point M and construct a parallelogram with \mathbf{v}_1 as its diagonal and \mathbf{v} as one of its sides. It is

* In general, for any variable vector \mathbf{u} depending on an argument t

$$\lim_{\Delta t \rightarrow 0} \frac{\Delta \mathbf{u}}{\Delta t} = \frac{d\mathbf{u}}{dt}.$$

evident that the other side will represent vector $\Delta \mathbf{v}$. Note that vector $\Delta \mathbf{v}$ is always directed towards the inside of the path.

The ratio of the velocity increment vector $\Delta \mathbf{v}$ to the corresponding time interval Δt defines the *vector of average acceleration of the particle* in the given time interval:

$$\mathbf{w}_{av} = \frac{\Delta \mathbf{v}}{\Delta t}.$$

Obviously, the vector of average acceleration has the same direction as vector $\Delta \mathbf{v}$, i.e., towards the inside of the path.

The instantaneous acceleration of a particle at a given time t is defined as the vector quantity \mathbf{w} towards which the average acceleration \mathbf{w}_{av} tends when the time interval Δt tends to zero:

$$\mathbf{w} = \lim_{\Delta t \rightarrow 0} \frac{\Delta \mathbf{v}}{\Delta t} = \frac{d\mathbf{v}}{dt},$$

or, taking into account Eq. (13),

$$\mathbf{w} = \frac{d\mathbf{v}}{dt} = \frac{d^2 \mathbf{r}}{dt^2}. \quad (14)$$

Fig. 143.

Thus, the vector of instantaneous acceleration of a particle is equal to the first derivative of the velocity vector, or the second derivative of the radius vector of the particle with respect to time.

It follows from Eq. (14) that the acceleration vector \mathbf{w} is equal to the ratio of the increment of the velocity vector $d\mathbf{v}$ to the corresponding time interval dt .

Let us see how vector \mathbf{w} is directed with respect to the path of the particle. If the path is a plane curve, the acceleration vector \mathbf{w} , like the vector \mathbf{w}_{av} , lies in the plane of the curve and is directed towards the inside of the curve.

If the path is a curve in space, the vector \mathbf{w}_{av} is directed towards its inside, in a plane through the tangent to the path at point M and a line parallel to the tangent through the neighbouring point M_1 (see Fig. 143). In the limit, when point M_1 tends to M , this plane coincides with the so-called *osculating plane**. Hence, in the general case, the acceleration vector \mathbf{w} lies in the osculating plane and is directed towards the inside of the curve.

* The osculating plane through a point M on a curve may also be defined as the limiting position of a plane through points M , M_1 , and M_2 of the given curve when points M_1 and M_2 tend to M . Of all the planes passing through point M , the osculating plane has the highest order of osculation (has the greatest contact with the curve). Every point of a three-dimensional curve (e.g., a helix) has its own osculating plane. The osculating plane of a plane curve is coincident with the plane of the curve and is common for all its points.

Eqs. (13) and (14) obtained in §§ 64 and 65 give the general expressions of the basic kinematic characteristics of motion in vector form and are essential for developing all other formulas and relationships in particle kinematics.

66. Theorem of the Projection of the Derivative of a Vector. The following theorem will be found useful in solving vector equations containing derivatives, when it is necessary to go over from relations between vectors to relations between their projections: *The projection of the derivative of a vector on a fixed axis is equal to the derivative of the projection of the differentiated vector on the same axis.*

Let there be a variable vector \mathbf{p} depending on an argument t . The derivative of \mathbf{p} with respect to t is also a vector \mathbf{q} . By definition,

$$\mathbf{q} = \lim_{\Delta t \rightarrow 0} \frac{\Delta \mathbf{p}}{\Delta t} = \lim_{\Delta t \rightarrow 0} \frac{\mathbf{p}_1 - \mathbf{p}}{\Delta t},$$

where \mathbf{p} and \mathbf{p}_1 are the values of the differentiated vector at instants t and t_1 . Applying the theorem of the projection of a vector sum (or difference) on an axis, we obtain:

$$q_x = \lim_{\Delta t \rightarrow 0} \frac{p_{1x} - p_x}{\Delta t},$$

where p_x and q_x are the projections of vectors \mathbf{p} and \mathbf{q} on the axis Ox . But $p_{1x} - p_x = \Delta p_x$. Hence,

$$q_x = \lim_{\Delta t \rightarrow 0} \frac{\Delta p_x}{\Delta t} = \frac{dp_x}{dt}.$$

The theorem is thus proved, as we have shown that

$$\text{if } \mathbf{q} = \frac{d\mathbf{p}}{dt}, \text{ then } q_x = \frac{dp_x}{dt}. \quad (15)$$

It should be noted that the relation of the form (15) is not valid for the magnitudes of vectors, i.e., if $\mathbf{q} = \frac{d\mathbf{p}}{dt}$, then generally $|q| \neq \frac{d|p|}{dt}$. In particular, we have proved that $\mathbf{v} = \frac{d\mathbf{r}}{dt}$ and $\mathbf{w} = \frac{d\mathbf{v}}{dt}$; here, too, in the general case $|v| \neq \frac{d|r|}{dt}$ and $|w| \neq \frac{d|v|}{dt}$.

For, say, if a particle moves in a circle whose centre is at the origin of a coordinate system, its velocity is $\mathbf{v} = \frac{d\mathbf{r}}{dt}$ (the direction of \mathbf{r} changes with time), but in magnitude $|r| = \text{const.}$, and consequently, $\frac{d|r|}{dt} = 0$. It is evident, then, that $|v| \neq \frac{d|r|}{dt}$. That $|w| \neq \frac{d|v|}{dt}$ will be shown in § 69.

The methods of determining the magnitudes of the velocity and acceleration of a particle are discussed further on.

67. Coordinate Method of Describing Motion. Determination of the Path, Velocity and Acceleration of a Particle. The position of a particle with respect to a given frame of reference $Oxyz$ can be specified by its cartesian coordinates x, y, z (Fig. 144). When

Fig. 144.

motion takes place, the three coordinates will change with time. If we want to know the equation of motion of a particle, i.e., its location in space at any instant, we must know its coordinates for any moment of time, i.e., the relations

$$x = f_1(t), \quad y = f_2(t), \quad z = f_3(t) \quad (16)$$

should be known.

Eqs. (16) are the equations of motion of a particle in terms of cartesian rectangular coordinate axes. They describe the curvilinear motion of a particle by the coordinate method*.

If a particle moves in one plane, then, taking that plane for the xy plane, we obtain two equations of motion:

$$x = f_1(t), \quad y = f_2(t). \quad (17)$$

Let us see how the kinematic characteristics of motion are determined by the coordinate method of describing the motion of a particle.

1) **Determination of the Path of a Particle.** Taking time t as the parameter in Eqs. (16) and (17), we notice that these equations are, in fact, the equations of the path of a particle in parametric form. To obtain the equation of the path in the usual form, i.e., in the form of a relation only between the coordinates of a particle M , time t must be eliminated from the equations of motion.

2) **Determination of the Velocity of a Particle.** The velocity vector of a particle is $\mathbf{v} = \frac{d\mathbf{r}}{dt}$. Hence, from relation (15), we obtain:

$$v_x = \frac{dr_x}{dt}, \quad v_y = \frac{dr_y}{dt}, \quad v_z = \frac{dr_z}{dt}.$$

But from the diagram in Fig. 144 we see that the projections of the radius vector \mathbf{r} of the particle on the coordinate axes are

* The motion of a particle can be described in other coordinate systems: polar, spherical, etc. In this case the formulas for determining \mathbf{v} and \mathbf{w} will be other than Eqs. (18)-(21) deduced in this section (see, for example, § 71).

equal to the coordinates of the particle, i.e., $r_x = x$, $r_y = y$, $r_z = z$. Therefore finally,

$$v_x = \frac{dx}{dt}, \quad v_y = \frac{dy}{dt}, \quad v_z = \frac{dz}{dt}, \quad (18)$$

i.e., the projections of the velocity on the coordinate axes are equal to the first derivatives of the corresponding coordinates of the particle with respect to time.

Knowing the projections of the velocity, we can find the magnitude and direction (i.e., the angles α , β , γ which vector \mathbf{v} makes with the coordinate axes) from the equations:

$$\left. \begin{aligned} v &= \sqrt{v_x^2 + v_y^2 + v_z^2}; \\ \cos \alpha &= \frac{v_x}{v}, \quad \cos \beta = \frac{v_y}{v}, \quad \cos \gamma = \frac{v_z}{v}. \end{aligned} \right\} \quad (19)$$

3) Determination of the Acceleration of a Particle. The acceleration vector of a particle is $\mathbf{w} = \frac{d\mathbf{v}}{dt}$. Hence, from the theorem of the projection of a derivative and from Eqs. (18), we obtain

$$w_x = \frac{dv_x}{dt} = \frac{d^2x}{dt^2}, \quad w_y = \frac{dv_y}{dt} = \frac{d^2y}{dt^2}, \quad w_z = \frac{dv_z}{dt} = \frac{d^2z}{dt^2}, \quad (20)$$

i.e., the projections of the acceleration on the coordinate axes are equal to the first derivatives of the projections of the velocities, or the second derivatives of the corresponding coordinates, of the particle with respect to time. The magnitude and direction of the acceleration are given by the equations

$$\left. \begin{aligned} w &= \sqrt{w_x^2 + w_y^2 + w_z^2}; \\ \cos \alpha_1 &= \frac{w_x}{w}; \quad \cos \beta_1 = \frac{w_y}{w}, \quad \cos \gamma_1 = \frac{w_z}{w}, \end{aligned} \right\} \quad (21)$$

where α_1 , β_1 , and γ_1 are the angles made by the acceleration vector with the coordinate axes.

Thus, if the motion of a particle is described in rectangular cartesian coordinates by Eqs. (16) and (17), the velocity of the particle is given by Eqs. (18) and (19) and the acceleration by Eqs. (20) and (21). In the case of plane motion, the z projection should be omitted in all the equations.

Solution of problems. As in the case of rectilinear motion, in order to solve a problem we must know the equations of motion of a given particle to find any of its kinematic characteristics. If the equations of motion are not given directly, the solution must begin with the deduction of these equations.

Problem 54. The motion of a particle is described by the equations

$$x = 8t - 4t^2, \quad y = 6t - 3t^2,$$

where x and y are in metres and t is in seconds.

Determine the path, velocity and acceleration of the particle.

Solution. To determine the path, we first eliminate time t from the equations of motion. Multiplying both parts of the first equation by 3 and both parts of the second by 4, and subtracting the second from the first, we obtain $3x - 4y = 0$, or

$$y = \frac{3}{4}x.$$

Consequently, the path is a straight line making an angle α with the x axis such that $\tan \alpha = \frac{3}{4}$ (Fig. 145).

Now let us determine the velocity of the particle. From Eqs. (18) and (19) we obtain

$$v_x = \frac{dx}{dt} = 8(1 - t), \quad v_y = \frac{dy}{dt} = 6(1 - t);$$

$$v = \sqrt{v_x^2 + v_y^2} = 10(1 - t).$$

To determine the acceleration of the particle, Eqs. (20) and (21) give us:

$$w_x = \frac{d^2x}{dt^2} = -8, \quad w_y = \frac{d^2y}{dt^2} = -6, \quad w = 10 \text{ m/sec}^2.$$

Vectors \mathbf{v} and \mathbf{w} are evidently directed along the path, i.e., along AB . As $w = \text{const.}$, the motion is uniformly variable. The projections of the acceleration on the coordinate axes are always negative,

consequently the acceleration is always directed from B to A . The projections of the velocity at $0 < t < 1$ are positive, consequently, within this time interval, the velocity is directed from O to B . At time $t = 0$, $v = 10 \text{ m/sec}$, and at time $t = 1 \text{ sec}$, $v = 0$. When $t > 1 \text{ sec}$, both projections of the velocity are negative and, consequently, the velocity is directed from B to A , i.e., similarly as the acceleration.

Fig. 145.

Finally, note that, at $t = 0$, $x = 0$ and $y = 0$; at $t = 1 \text{ sec}$, $x = 4$ and $y = 3$ (point B); at $t = 2 \text{ sec}$, $x = 0$, $y = 0$; at $t > 2$, the absolute values of x and y continue to increase in the negative direction.

Thus, the equations given in the statement of the problem tell us everything about the motion of the particle. The motion begins at point O with an initial velocity $v_0 = 10 \text{ m/sec}$ and is along a straight line AB inclined to the x axis at an angle α such that $\tan \alpha = \frac{3}{4}$. On the portion OB the motion is uniformly retarded, and in one second the particle comes to rest at point $B(4, 3)$. From there it moves back with uniform acceleration. At $t = 2 \text{ sec}$, the particle returns to the origin of coordinates and continues to move along OA . The acceleration is all the time 10 m/sec^2 .

Problem 55. The motion of a particle is described by the equations:

$$x = a \sin \omega t, \quad y = a \cos \omega t, \quad z = ut,$$

where a , ω , and u are constants. Determine the path, velocity and acceleration of the particle.

Solution. Squaring the first two equations and adding them, we obtain (since $\sin^2 \omega t + \cos^2 \omega t = 1$):

$$x^2 + y^2 = a^2.$$

Hence, the path lies on a circular cylinder of radius a , the axis of which is coincident with the z axis (Fig. 146). Determining t from the third equation and substituting its value into first, we find:

$$x = a \sin \left(\frac{\omega}{u} z \right).$$

Thus, the path of the particle is the line of intersection of a sinusoidal surface, whose generators are parallel to the y axis, with the cylindrical surface of radius a . This curve is called a *screw*. It can be seen from the equations of motion that the particle makes one turn along the screw line in time t_1 , determined by the equation $\omega t_1 = 2\pi$. The displacement of the particle parallel to the z axis in that time is $h = ut_1 = \frac{2\pi u}{\omega}$ and is called the *pitch* of the screw.

Let us now determine the velocity and acceleration of the particle. Differentiating the equations of motion with respect to time, we obtain:

$$v_x = a\omega \cos \omega t, \quad v_y = -a\omega \sin \omega t, \quad v_z = u,$$

whence

$$v = \sqrt{a^2\omega^2 (\cos^2 \omega t + \sin^2 \omega t) + u^2} = \sqrt{a^2\omega^2 + u^2}.$$

The quantities under the radical are constant. Consequently, the magnitude of the velocity is constant and is directed at a tangent to the path. From Eqs. (20) we calculate the projections of the acceleration:

$$w_x = -a\omega^2 \sin \omega t, \quad w_y = -a\omega^2 \cos \omega t, \quad w_z = 0,$$

whence

$$w = \sqrt{w_x^2 + w_y^2} = a\omega^2.$$

Thus, the motion has an acceleration of constant magnitude. To determine the direction of acceleration, we have the equations

$$\cos \alpha_1 = \frac{w_x}{w} = -\sin \omega t = -\frac{x}{a},$$

$$\cos \beta_1 = \frac{w_y}{w} = -\cos \omega t = -\frac{y}{a}, \quad \cos \gamma_1 = \frac{w_z}{w} = 0.$$

But evidently

$$\frac{x}{a} = \cos \alpha, \quad \frac{y}{a} = \cos \beta,$$

where α and β are the angles made by the radius a , drawn from the axis of the cylinder to the moving particle, with the x and y axes. As the cosines of

Fig. 146.

angles α_1 and β_1 differ from the cosines of the angles α and β only in sign, we conclude that the acceleration of the particle is continuously directed along the radius of the cylinder towards its axis.

It should be noted that although, in the present case, the motion has a velocity of constant magnitude (i.e., has a constant *speed*), the acceleration of the particle is not zero, as the direction of velocity is continually changing.

Problem 56. Determine the path, velocity and acceleration of point M in the middle of the connecting rod of the crankgear in Fig. 147, if $OA = AB = 2a$ and angle φ increases in proportion with time: $\varphi = \omega t$.

Solution. Let us first develop the equations of motion of point M . Drawing the coordinate axes as shown and denoting the coordinates of M by x and y , we obtain:

$$x = 2a \cos \varphi + a \cos \varphi, \\ y = a \sin \varphi.$$

Fig. 147.

Substituting the expression for φ , we obtain the equations of motion of point M :

$$x = 3a \cos \omega t, \quad y = a \sin \omega t.$$

To determine the path of M we write the equations of motion in the form

$$\frac{x}{3a} = \cos \omega t, \quad \frac{y}{a} = \sin \omega t.$$

Squaring these equations and adding them, we obtain:

$$\frac{x^2}{9a^2} + \frac{y^2}{a^2} = 1.$$

Thus, the path described by point M is an ellipse with semiaxes equal to $3a$ and a .

From Eqs. (18) and (19) we determine the velocity of point M :

$$v_x = -3a\omega \sin \omega t, \quad v_y = a\omega \cos \omega t;$$

$$v = a\omega \sqrt{9 \sin^2 \omega t + \cos^2 \omega t}.$$

We see that the velocity is a variable quantity, changing with time from $v_{\min} = a\omega$ to $v_{\max} = 3a\omega$.

Now, from Eqs. (20), we determine the projections of the acceleration of point M :

$$w_x = -3a\omega^2 \cos \omega t = -\omega^2 x, \quad w_y = -a\omega^2 \sin \omega t = -\omega^2 y,$$

whence

$$w = \sqrt{\omega^4 (x^2 + y^2)} = \omega^2 r,$$

where r is the radius vector from the origin to point M . Thus, the magnitude of the acceleration of the point changes in proportion to its distance from the centre of the ellipse.

To determine the direction of ω , we have, from Eqs. (21):

$$\cos \alpha_1 = \frac{\omega_x}{\omega} = -\frac{x}{r}, \quad \cos \beta_1 = \frac{\omega_y}{\omega} = -\frac{y}{r}.$$

We see that, as in problem 55, the acceleration of point M is continually directed along MO towards the centre of the ellipse.

68. Natural Method of Describing Motion. Determination of the Velocity of a Particle. The natural method of describing motion is convenient when the path of a particle is known at once. Let a particle M be moving with respect to a frame of reference O, x, y, z , along an arbitrary path AB (Fig. 148). Take any fixed point O on the path as the origin of another frame of reference; now, taking the path as an arc-coordinate axis, assume the positive and negative directions, as is done with rectangular axes. The position of the particle M on the path is now specified by a single coordinate s , equal to the distance from O to M measured along the arc of the path and taken with the appropriate sign. When M moves, the distance s changes with time. In order to know the position of M on the path at any instant, we must know the relation

Fig. 148.

$$s = f(t). \quad (22)$$

Eq. (22) expresses the law of motion of the particle M along its path.

Thus, in order to describe the motion of a particle by the natural method, a problem must state: 1) the path of the particle; 2) the origin on the path, showing the positive and negative directions; 3) the equation of the particle's motion along the path in the form $s = f(t)$, where the distance $s = OM$ gives the arc coordinate of the particle.

Fig. 149.

The dependence of s on t may be shown graphically, as in the case of rectilinear motion (§ 61). Here, of course, the distance of s , instead of x , should be laid off along the ordinate axis.

Let us see how the velocity of a particle can be determined when the motion is described by the natural method. If in some time interval $\Delta t = t_1 - t$ a particle moves from position M to position M_1 , the displacement along the arc of the path being

$\Delta s = s_1 - s$ (Fig. 149), the numerical value of the average velocity will be*:

$$v_{av} = \frac{s_1 - s}{t_1 - t} = \frac{\Delta s}{\Delta t}. \quad (23)$$

Passing to the limit, we obtain the numerical value of the instantaneous velocity for a given time t :

$$v = \lim_{\Delta t \rightarrow 0} \frac{\Delta s}{\Delta t} \text{ or } v = \frac{ds}{dt}. \quad (24)$$

Thus, the numerical value of the instantaneous velocity of a particle is equal to the first derivative of the displacement (of the arc coordinate) s of the particle with respect to time.

The velocity vector is tangent to the path, the latter assumed to be known. As in the case of rectilinear motion, if $v > 0$, the velocity vector \mathbf{v} is in the positive direction of s , if $v < 0$, \mathbf{v} is in the negative direction of s . Thus, the numerical value of the velocity defines simultaneously the modulus and the direction of the velocity vector. Eq. (24) also shows that v can be calculated as the ratio of the infinitesimal displacement ds of a particle along the arc of its path to the corresponding time interval dt .

69. Tangential and Normal Acceleration of a Particle. Let us now determine the acceleration of a particle. As the vector of acceleration \mathbf{w} of a particle always lies in an osculating plane (see § 65), the former can be determined if we obtain the projections of the vector on any two axes in such a plane.

Fig. 150.

Let us draw one axis along the tangent $M\tau$ to the path in the direction of the positive displacement s (Fig. 150), and the other along the normal Mn towards the inside of the path. The normal Mn , which lies in the osculating plane (or in the plane of the curve itself if the curve is two-dimensional), is called the *principal normal*.

The two axes—the tangent and principal normal—have as their origin the moving particle M and move with it in space.

* It will be noticed that the values of v_{av} as obtained from Eqs. (23) and (12') do not coincide with each other (the first specifying v_{av} for motion along an arc, the second for the shortest path from M to M_1). In the limit, however, when $\Delta t \rightarrow 0$, both equations give the same result for v , since in the limit the ratio of arc Δs to chord MM_1 is unity. On the concept of "numerical value" of velocity see footnote on p. 130.

Let the particle occupy a position M and have a velocity \mathbf{v} at any time t , and at time $t_1 = t + \Delta t$ let it occupy a position M_1 and have a velocity \mathbf{v}_1 . Then, by virtue of the definition,

$$\mathbf{w} = \lim_{\Delta t \rightarrow 0} \frac{\Delta \mathbf{v}}{\Delta t} = \lim_{\Delta t \rightarrow 0} \frac{\mathbf{v}_1 - \mathbf{v}}{\Delta t}.$$

Let us now express this equation in terms of the projections of the vectors on the axes $M\tau$ and Mn through point M (see Fig. 150). From the theorem of the projection of a vector sum (or difference) on an axis we obtain:

$$w_\tau = \lim_{\Delta t \rightarrow 0} \frac{v_{1\tau} - v_\tau}{\Delta t},$$

$$w_n = \lim_{\Delta t \rightarrow 0} \frac{v_{1n} - v_n}{\Delta t}.$$

Fig. 151.

Draw through point M_1 a line ab parallel to $M\tau$ and denote the angle between the vector \mathbf{v}_1 and the tangent $M\tau$ by the symbol $\Delta\varphi$. This angle between the tangents to the curve at point M and M_1 is called the *angle of contiguity*.

It will be recalled that the limit of the ratio of the angle of contiguity $\Delta\varphi$ to the arc $\widehat{MM_1} = \Delta s$ defines the curvature k of the curve at point M . As the curvature is the inverse of the radius of curvature ϱ at M , we have:

$$\lim_{\Delta s \rightarrow 0} \frac{\Delta\varphi}{\Delta s} = k = \frac{1}{\varrho}.$$

From the diagram in Fig. 150, we see that the projections of vectors \mathbf{v} and \mathbf{v}_1 on the axis $M\tau$ and Mn are

$$\begin{aligned} v_\tau &= v, & v_n &= 0, \\ v_{1\tau} &= v_1 \cos \Delta\varphi, & v_{1n} &= v_1 \sin \Delta\varphi, \end{aligned}$$

where v and v_1 are the numerical values of the velocity of the particle at instants t and t_1 . Hence,

$$w_\tau = \lim_{\Delta t \rightarrow 0} \frac{v_1 \cos \Delta\varphi - v}{\Delta t}, \quad w_n = \lim_{\Delta t \rightarrow 0} \left(v_1 \frac{\sin \Delta\varphi}{\Delta t} \right).$$

It will be noted that when $\Delta t \rightarrow 0$, point M_1 approaches M indefinitely, and simultaneously $\Delta\varphi \rightarrow 0$, $\Delta s \rightarrow 0$, and $v_1 \rightarrow v$.

Hence, taking into account that $\lim_{\Delta\varphi \rightarrow 0} (\cos \Delta\varphi) = 1$, we obtain for w_τ the expression: $w_\tau = \lim_{\Delta t \rightarrow 0} \frac{v_1 - v}{\Delta t} = \frac{dv}{dt}.$

Multiplying the numerator and denominator of the fraction in the expression of ω_n by $\Delta\varphi\Delta s$, we find

$$\omega_n = \lim_{\Delta t \rightarrow 0} \left(v_1 \frac{\sin \Delta\varphi}{\Delta\varphi} \frac{\Delta\varphi}{\Delta s} \frac{\Delta s}{\Delta t} \right) = \frac{v^2}{\rho},$$

since, when $\Delta t \rightarrow 0$, the limits of each of the cofactors inside the brackets are

$$\lim v_1 = v, \quad \lim \frac{\sin \Delta\varphi}{\Delta\varphi} = 1, \quad \lim \frac{\Delta\varphi}{\Delta s} = \frac{1}{\rho}, \quad \lim \frac{\Delta s}{\Delta t} = \frac{ds}{dt} = v.$$

Finally we obtain

$$\omega_\tau = \frac{dv}{dt} = \frac{d^2s}{dt^2}; \quad \omega_n = \frac{v^2}{\rho}. \quad (25)$$

We have thus proved that *the projection of the acceleration of a particle on the tangent to the path is equal to the first derivative of the numerical value of the velocity, or the second derivative of the displacement (the arc coordinate) s , with respect to time; the projection of the acceleration on the principal normal is equal to the second power of the velocity divided by the radius of curvature of the path at the given point of the curve.* This is an important theorem of particle kinematics.

Let us lay off vectors \mathbf{w}_τ and \mathbf{w}_n (equal in scalar magnitude to ω_τ and ω_n) along the tangent $M\tau$ and principal normal Mn respectively (Fig. 151). These vectors are the normal and tangential components of the acceleration of the particle. Component \mathbf{w}_n is always directed along the inward normal (the value of ω_n is always positive), while component \mathbf{w}_τ can be directed either in the positive or the negative direction of the axis $M\tau$ depending on the sign of the projection ω_τ (see Fig. 151a and b).

The acceleration vector \mathbf{w} is the diagonal of a parallelogram constructed with components \mathbf{w}_τ and \mathbf{w}_n as its sides. As the components are mutually perpendicular, in magnitude

$$w = \sqrt{\omega_\tau^2 + \omega_n^2} = \sqrt{\left(\frac{dv}{dt}\right)^2 + \left(\frac{v^2}{\rho}\right)^2}. \quad (26)$$

The angle μ between vector \mathbf{w} and the normal Mn is determined by the formula

$$\tan \mu = \frac{|\omega_\tau|}{\omega_n}. \quad (27)$$

Thus, if the motion of a particle is described by the natural method and the path (and, consequently, the radius of curvature at any point) and the equations of motion (22) are known, from Eqs. (24) and (25)-(27) we can determine the magnitude and direction

of the velocity and acceleration vectors of the particle for any instant*.

70. Some Special Cases of Particle Motion. Using the results obtained above, let us investigate some special cases of particle motion.

1) **Rectilinear Motion.** If the path of a particle is a straight line, then $\varrho = \infty$, and $\omega_n = \frac{v^2}{\varrho} = 0$ and the total acceleration is equal to the tangential acceleration:

$$w = w_\tau = \frac{dv}{dt}.$$

As in this case the velocity changes only in magnitude, we conclude that *the tangential acceleration characterises the change of speed.*

2) **Uniform Curvilinear Motion.** Curvilinear motion is uniform when the speed is constant: $v = \text{const.}$ Then $\omega_\tau = \frac{dv}{dt} = 0$, and the total acceleration of the particle is equal to the normal acceleration:

$$w = w_n = \frac{v^2}{\varrho}.$$

The acceleration vector w is continuously directed along the normal to the path of the particle.

As in this case acceleration is represented only by the change in the direction of the velocity, we conclude that *the normal acceleration characterises the change of direction of the velocity.*

Let us deduce the equation of uniform curvilinear motion. From Eq. (24) we have $\frac{ds}{dt} = v$, or $ds = v dt$.

Let a particle be at the initial time ($t=0$) at a distance s_0 from the origin. Then, integrating both members of the equation over the respective intervals, we have

$$\int_{s_0}^s ds = \int_0^t v dt \quad \text{or} \quad s - s_0 = vt,$$

as $v = \text{const.}$ Finally, we obtain the equation of uniform curvilinear motion in the form

$$s = s_0 + vt. \quad (28)$$

* From Eq. (26) it is evident that in the general case $w \neq \frac{dv}{dt}$, which was already pointed out at the end of § 66.

3) **Uniform Rectilinear Motion.** In this case $\omega_n = \omega_\tau = 0$, therefore, $\omega = 0$. Note that *uniform rectilinear motion is the only case of motion in which the acceleration is continually zero.*

4) **Uniformly Variable Curvilinear Motion.** Curvilinear motion is called uniformly variable if the *tangential acceleration* is constant: $\omega_\tau = \text{const.}$ Let us write the equation of this motion, assuming that, at $t=0$, $s=s_0$ and $v=v_0$, where v_0 is the initial velocity of a particle. By Eq. (25), $\frac{dv}{dt} = \omega_\tau$, or $dv = \omega_\tau dt$.

As $\omega_\tau = \text{const.}$, integrating both members of the last equation over the corresponding intervals gives us:

$$v = v_0 + \omega_\tau t. \quad (29)$$

Let us write Eq. (29) in the form

$$\frac{ds}{dt} = v_0 + \omega_\tau t \quad \text{or} \quad ds = v_0 dt + \omega_\tau t dt.$$

Integrating again, we obtain the equation of uniformly variable curvilinear motion of a particle in the form

$$s = s_0 + v_0 t + \omega_\tau \frac{t^2}{2}. \quad (30)$$

The velocity of this motion is given by Eq. (29).

The difference between Eqs. (29) and (30) and the corresponding Eqs. (9) and (8) for rectilinear motion is that instead of the acceleration ω , the former have the tangential acceleration ω_τ , and instead of the rectangular coordinate x they have the arc coordinate s .

Fig. 152.

If, in curvilinear motion, the magnitude of the velocity increases, the motion is said to be accelerated, if it decreases, the motion is said to be retarded. As the change of magnitude of the velocity is characterised by the tangential acceleration, the motion is accelerated if v and ω_τ have the same sign, i.e., the angle between vectors \mathbf{v} and \mathbf{w} is acute (see Fig. 152a), and retarded if the signs are different (the angle between \mathbf{v} and \mathbf{w} is obtuse, see Fig. 152b).

Solution of Problems. As pointed out before, in order to solve problems of kinematics, we must know the equations of motion for a given particle. If the motion is described by the

natural method (the path and the equation of motion along it are given) all its characteristics are found from the equations developed in §§ 68-70. If the motion is described by the coordinate method, its characteristics (including the tangential and normal accelerations and the radius of curvature of the path) can be found as in Problem 59.

Problem 57. Small oscillations of the pendulum shown in Fig. 153 are represented by the equation of motion $s = a \sin kt$ (the origin is at O , a and k are constants). Determine the velocity, tangential and normal accelerations of the bob and the positions at which they become zero if the bob describes a circular arc of radius l .

Solution. From the respective equations we find:

$$v = \frac{ds}{dt} = ak \cos kt; \quad w_t = \frac{dv}{dt} = -ak^2 \sin kt,$$

$$w_n = \frac{v^2}{l} = \frac{a^2 k^2}{l} \cos^2 kt.$$

Fig. 153.

The equation of motion is that of simple harmonic motion, the amplitude of swing being a . In the extreme positions A and B , $\sin kt = \pm 1$, and consequently, $\cos kt = 0$. Hence, in positions A and B , the velocity and normal acceleration are zero and the tangential acceleration has its maximum value $w_{t \max} = ak^2$. At the origin O , where $s = 0$, the reverse is true, and $\sin kt = 0$ while $\cos kt = 1$. In this position, $w_t = 0$ and v and w_n have their maximum values:

$$v_{\max} = ak, \quad w_{n \max} = \frac{a^2 k^2}{l}.$$

We observe from this example that in non-uniform curvilinear motion w_t or w_n may become zero at different points of the path, specifically, $w_t = 0$ wherever

$$\frac{dv}{dt} = 0,$$

i.e., for example, where v is at its maximum or minimum; $w_n = 0$ at the points where $v = 0$ (as in the present case) or where $\rho = \infty$ (the points of inflection of the path).

Problem 58. A train starts moving from rest with uniform acceleration along a curve of radius $R = 800$ m and reaches a velocity $v_1 = 36$ km/h after travelling a distance $s_1 = 600$ m. Determine the velocity and acceleration of the train at the middle of this distance.

Solution. As the train moves with uniform acceleration and $v_0 = 0$, its equation of motion (assuming $s_0 = 0$) is

$$s = \frac{1}{2} w_t t^2,$$

and its velocity is

$$v = w_t t.$$

Eliminating time t from these equations, we obtain

$$v^2 = 2w_t s.$$

According to the conditions of the problem, at $s = s_1$, $v = v_1$, whence we find.

$$\omega_\tau = \frac{v_1^2}{2s_1}.$$

At the middle of the path, where $s_2 = \frac{s_1}{2}$, the velocity v_2 is:

$$v_2 = \sqrt{2\omega_\tau s_2} = \sqrt{\omega_\tau s_1} = \frac{v_1}{\sqrt{2}}.$$

The normal acceleration at this point of the path is:

$$\omega_{n2} = \frac{v_2^2}{R} = \frac{v_1^2}{2R}.$$

Knowing ω_τ and ω_{n2} , we find the total acceleration of the train at the middle of the curve:

$$\omega_2 = \sqrt{\omega_\tau^2 + \omega_{n2}^2} = \frac{v_1^2}{2} \sqrt{\frac{1}{s_1^2} + \frac{1}{R^2}}.$$

Substituting the numerical values, we obtain:

$$v_2 \approx 7.1 \text{ m/sec}, \quad \omega_2 = \frac{5}{48} \approx 0.1 \text{ m/sec}^2.$$

Problem 59. The equations of motion for a particle thrown with a horizontal velocity are:

$$x = v_0 t, \quad y = \frac{1}{2} g t^2,$$

where v_0 and g are constants.

Determine the path, velocity and acceleration of the particle, its tangential and normal accelerations and the radius of curvature of its path at any point, expressing them in terms of the velocity of the particle at the given point.

Solution. Determining t from the first equation and substituting its expression into the second, we obtain

$$y = \frac{g}{2v_0^2} x^2.$$

The path of the particle is a parabola (Fig. 154).

Differentiating the equation of motion with respect to time, we find:

$$v_x = \frac{dx}{dt} = v_0; \quad v_y = \frac{dy}{dt} = gt,$$

whence

$$v = \sqrt{v_0^2 + g^2 t^2}. \quad (a)$$

Thus, at the initial moment ($t=0$) the velocity of the particle $v = v_0$ and it continuously increases with time.

Let us now determine the acceleration of the particle. From the respective equations we have:

$$\omega_x = \frac{d^2 x}{dt^2} = 0, \quad \omega_y = \frac{d^2 y}{dt^2} = g.$$

Fig. 154.

Consequently, the acceleration is

$$\omega = g.$$

In the present case the particle has an acceleration of constant magnitude and direction, parallel to the y axis. Note that, although $\omega = \text{const.}$, the motion of the particle is not uniformly variable, since the condition for uniformly variable motion is not $\omega = \text{const.}$, but $\omega_\tau = \text{const.}$ In this case, we shall find, ω_τ is not constant.

Knowing the dependence of v on t [formula (a)], we can find ω_τ :

$$\omega_\tau = \frac{dv}{dt} = \frac{g^2 t}{\sqrt{v_0^2 + g^2 t^2}} = \frac{g^2 t}{v}.$$

But from equation (a) we have $v^2 = v_0^2 + g^2 t^2$, and consequently,

$$t = \frac{1}{g} \sqrt{v^2 - v_0^2}.$$

Substituting this expression of t , we express ω_τ in terms of the velocity v :

$$\omega_\tau = g \sqrt{1 - \frac{v_0^2}{v^2}}.$$

It follows that at the initial moment, when $v = v_0$, $\omega_\tau = 0$, then increasing together with v and, at $v \rightarrow \infty$, $\omega_\tau \rightarrow g$. Thus, in the limit the tangential acceleration approaches the total acceleration g .

To determine ω_n , we refer to the equation

$$\omega^2 = \omega_\tau^2 + \omega_n^2,$$

whence

$$\omega_n^2 = \omega^2 - \omega_\tau^2 = g^2 - g^2 \left(1 - \frac{v_0^2}{v^2}\right) = g^2 \frac{v_0^2}{v^2},$$

and

$$\omega_n = \frac{v_0 g}{v}.$$

Thus, at the initial moment ($v = v_0$), $\omega_n = g$, decreasing as v increases and in the limit approaching zero.

To determine the radius of curvature of the path, we use the equation

$$\omega_n = \frac{v^2}{\rho},$$

whence

$$\rho = \frac{v^2}{\omega_n} = \frac{v^3}{v_0 g}.$$

At the initial moment the radius of curvature has its smallest value

$$\rho_{\min} = \frac{v_0^2}{g}.$$

As v increases, the radius of curvature increases, and consequently, the curvature of the path decreases. As $v \rightarrow \infty$, $\rho \rightarrow \infty$, and the curvature tends to zero.

71. Velocity in Polar Coordinates. If a particle moves in a plane, its position can be specified by its polar coordinates r and φ (Fig. 155). As the particle moves, these coordinates change with time, the motion of the particle in polar coordinates being given by the equations

$$r = f_1(t), \quad \varphi = f_2(t). \quad (31)$$

The numerical value of the velocity of the particle is $\frac{ds}{dt}$, i.e., it is equal to the ratio of the infinitesimal displacement ds to the time interval dt . In this case the displacement ds is the geometrical sum of the radial displacement, equal in magnitude to dr , and the transverse displacement perpendicular to the radius and

Fig. 155.

equal in magnitude to $r d\varphi$. The velocity \mathbf{v} is thus the geometrical sum of the radial velocity \mathbf{v}_r and the transverse velocity \mathbf{v}_φ , whose scalar magnitudes are, respectively,

$$v_r = \frac{dr}{dt}, \quad v_\varphi = r \frac{d\varphi}{dt}. \quad (32)$$

As \mathbf{v}_r and \mathbf{v}_φ are mutually perpendicular,

$$v = \sqrt{v_r^2 + v_\varphi^2} = \sqrt{\left(\frac{dr}{dt}\right)^2 + r^2 \left(\frac{d\varphi}{dt}\right)^2}. \quad (33)$$

Eqs. (32) and (33) give the velocity of a particle moving in a plane in polar coordinates.

72. Graphical Analysis of Particle Motion. The graphical method of solving problems of particle kinematics is useful when the analytical expression of the relationship $s = f(t)$ [or, in rectilinear motion, $x = f(t)$] is too involved, or when the motion is described by graphs obtained experimentally or plotted by recording instruments.

If we have a graph of motion expressing the displacement-time relationship (Fig. 156), we can plot a velocity curve by the method of graphical differentiation. It is apparent from the diagram that the average velocity of the given particle in the time interval $\Delta t = t_2 - t_1$ is given by the tangent of the angle which the secant K_1K_2 makes with the horizontal, as

$$v_{av} = \frac{s_2 - s_1}{t_2 - t_1} = \frac{\Delta s}{\Delta t} = \tan \alpha,$$

the accuracy depending on the scale factor.

The velocity of the particle at the given time t_1 is specified by the tangent of the angle made by the tangent to the curve through point K_1 , as

$$v_1 = \left(\frac{dv}{dt} \right)_{t=t_1} = \tan \alpha_1. \quad (34)$$

also within the scale factor.

Thus, by drawing tangents to the displacement curve at points K_1, K_2, \dots we can find the corresponding velocities at instants t_1, t_2, \dots from the tangents of the respective angles to the horizontal and plot a velocity curve. Similarly we can plot a curve for the tangential acceleration

$w_t = \frac{dv}{dt}$. The order to be followed in plotting the curves is explained in the solution of Problem 60.

To plot the curves of the normal and total acceleration (in the case of curvilinear motion) the values of w_n and w at different moments are computed from the corresponding equations. The values of v and w_t are taken from the plotted velocity and tangential acceleration curves, and ρ is determined from the given path.

If the velocity curve is known for a given motion, it is easy to plot a displacement curve by the method of graphical integration. As $ds = v dt$, then, assuming $s_0 = 0$, we have

$$s = \int_0^t v dt.$$

The integral in the right-hand side is computed as the respective area, taken with a plus for positive values of v and a minus for negative values.

Fig. 157.

For greater convenience in computing areas, the curve should be plotted on graph paper: the area is then obtained by simply counting the squares. In the case in Fig. 157, the displacement s_1 at time t_1 is equal to the difference between the upper and lower shaded areas multiplied by a scale factor*. By determining s for different instants t , we can plot a displacement curve. A tangential acceleration curve can be used in the same way to plot a velocity curve.

Problem 60. To investigate graphically the motion of a piston of a crankshaft mechanism (Fig. 158), if the crank is of length $O'A = 0.2$ m, the connecting rod is of length $AB = 0.4$ m, and the crank rotates uniformly, making one revolution in time $T = 1.6$ sec.

Solution. 1) Plotting the displacement curve for the piston. The following operations should be performed:

a) Choose scales for the displacement x and the time t . If you are using graph paper, remember that the error in measurement can be as high as

* The sum of these areas defines the distance travelled by the particle in time t_1 if $s_0 = 0$.

Fig. 156.

± 0.25 to 0.5 mm (depending on the quality of the paper and the drawing). Let us take a scale of 0.1 m to 1 cm for x , and 0.2 sec to 1 cm for t .

b) Draw a schematic design of the mechanism to the scale chosen for x (Fig. 158a): we have $O'A_0 = 2$ cm and $A_0B_0 = 4$ cm. Draw the coordinate axis $O'x$ coincident with the path of the piston. Divide the semicircle along which point A travels into 8 equal parts (the greater the number of parts, the more accurate the graph). Point A travels along each part in 0.1 sec. Set the legs

Fig. 158.

of your compass 4 cm apart (the distance AB) and from the end of each arc of the semicircle make an intercept on the axis $O'x$. These intercepts give the values of x for the instants t equal to $0, 0.1$ sec, 0.2 sec, etc.

c) The obtained plots of x and t give us the points for plotting the displacement curve for the piston through one revolution of the crank (Fig. 158b); the right-hand branch of the curve in this case is symmetrical to the left-hand branch.

2) Plotting the velocity curve.

a) Draw axes v and t (Fig. 158c) to the same scale of t as in Fig. 158b. Lay off along the t axis a segment O_1K_0 , which denotes one second to the given scale ($O_1K_0 = 5$ cm).

b) Determine the direction of the tangent to the curve $x = f(t)$ at point C_1 corresponding to time $t_1 = 0.1$ sec *. Draw through point K_0 a line K_0D_0 parallel to the tangent (the dashed line in Fig. 158c). Segment O_1D_0 specifies the velocity at time $t_1 = 0.1$ sec, since $O_1K_0 = 1$ sec and, from Eq. (34),

$$(v)_{t=0.1 \text{ sec}} = \tan \alpha_1 = \frac{O_1D_0}{O_1K_0} = O_1D_0.$$

If the scale of the displacement x is 1 cm to 0.1 m, the scale of the velocity v will be 1 cm to 0.1 m/sec. If the scale is inconvenient for drawing, being too large or too small, it can be altered as shown below.

c) In our case the scale of v is too large. Let us reduce it by three. For this lay off from O_1 a segment $O_1K = \frac{1}{3} O_1K_0$. Draw through K a line KD_1 parallel to the tangent through point C_1 (or to line K_0D_0). Segment O_1D_1 now defines the velocity at time $t_1 = 0.1$ sec to the scale 1 cm to 0.3 m/sec (the scale of v).

Drawing D_1E_1 parallel to axis O_1t , we obtain point E_1 of the velocity curve.

Similarly, by drawing through K lines KD_2, KD_3, \dots parallel to the tangents through point C_2, C_3, \dots we obtain points E_2, E_3, \dots , joining which in a continuous curve, we obtain the velocity graph for the piston (Fig. 158c).

3) Plotting the acceleration curve from the velocity curve (or the tangential acceleration curve if the motion is curvilinear). The procedure is analogous to the procedure for plotting the velocity curve from the displacement curve. Fig. 158d gives the acceleration curve for the piston to the scale 1 cm to 2.5 m/sec².

Problem 61. Determine by graphical construction the contour of the cam in Fig. 159a, such that when it rotates uniformly about its axle O' , the motion of rod AB will be as described by the curve in Fig. 159b, where T is the period of one revolution of the cam. During the first quarter revolution the rod moves up 0.2 m, during the second quarter revolution it remains motionless, and during the second half revolution it returns to its initial position. Also plot the velocity and acceleration curves for the rod. The scale of the displacement curve is 1 cm to 0.1 m.

Solution. Let us plot the contour of the cam to the same scale as the given displacement curve. For this draw a circle of radius 3 cm with its centre at O' and divide it into 16 equal parts. Also divide segment OT on the t axis of the graph into 16 equal parts. Lay off the value of x for each instant of time along the corresponding radii from the centre O' ($O'A_0 = Oa_0$, $O'A_1 = ba_1$, etc.). Joining points A_0, A_1 , etc., in a smooth curve, we obtain the required contour of the cam.

If the shape of the cam were given, we could plot the displacement curve for the rod AB by a similar construction.

By specifying any time T for one revolution of the cam, we can construct the velocity and acceleration curves for the rod AB as in the previous problem.

* A convenient instrument for drawing a tangent through a given point of a curve is a ruler with a reflecting surface perpendicular to the plane of the ruler (you can make such an instrument yourself by pasting a strip of smoothed aluminium foil to the side of your slide rule). Now place your ruler approximately perpendicular to the curve at the required point and turn it till the curve and its reflection make a continuous line. In this position the ruler gives the direction of the normal, the perpendicular to which through the given point is the tangent at that point. If you are using a strip of foil instead of a mirror, better draw the curve in Indian ink.

Fig. 159.

The curves are given in Figs 159c and d. As stated in the conditions of the problem, the velocity and acceleration of the rod are zero during the second quarter revolution of the cam. The velocity of the rod changes continuously, but the acceleration jumps at instants $t_1 = \frac{1}{4}T$ and $t_2 = \frac{1}{2}T$.

Chapter 11

TRANSLATORY AND ROTATIONAL MOTION OF A RIGID BODY

73. Motion of Translation. In kinematics, as in statics, we shall regard all solids as perfectly rigid bodies, i. e., we shall assume that the distance between any two points of a body remains the same during the whole period of motion.

Problems of kinematics of rigid bodies are basically of two types: 1) definition of the motion and analysis of the kinematic characteristics of the motion of a body as a whole; 2) analysis of the motion of every point of the body in particular.

We shall begin with the consideration of the motion of translation of a rigid body.

Translation of a rigid body is such a motion in which any straight line through the body remains continually parallel to itself.

Translation should not be confused with rectilinear motion. In translation the particles of a body may move on any curved paths. Here are some examples of translation.

1. When a motor car travels along a horizontal road, the motion of its body is that of translation, since every point of the body moves on a straight-line path.

2. The motion of the connecting rod AB in Fig. 160 is also that of translation, since, when the cranks O_1A and O_2B ($O_1A = O_2B$) rotate, any straight line through the rod remains parallel to itself.

Fig. 160.

The properties of translatory motion are defined by the following theorem: *In translatory motion, all the particles of a body move along similar paths (which will coincide if superimposed) and have at any instant the same velocity and acceleration.*

To prove the theorem, consider a rigid body translated with reference to a system of axes $Oxyz$. Take two arbitrary points A and B on the body whose positions at time t are specified by radius vectors \mathbf{r}_A and \mathbf{r}_B (Fig. 161). Draw a vector \overline{AB} joining the two points. It is evident that

$$\mathbf{r}_B = \mathbf{r}_A + \overline{AB}. \quad (35)$$

The length of AB is constant, being the distance between two points of a rigid body, and the direction of \overline{AB} is constant by virtue of the translatory motion of the body. Thus, the vector \overline{AB} is constant throughout the motion of the body ($\overline{AB} = \text{const.}$).

It follows, then, from Eq. (35) (and the diagram) that the path of particle B can be obtained by a parallel displacement of all the points of the path of particle A through a constant vector \overline{AB} . Hence, the paths of particles A and B are identical curves which will coincide if superimposed.

To determine the velocities of points A and B , we differentiate both parts of Eq. (35) with respect to time. We have

$$\frac{d\mathbf{r}_B}{dt} = \frac{d\mathbf{r}_A}{dt} + \frac{d(\overline{AB})}{dt}.$$

But the derivative of the constant vector \overline{AB} is zero while the derivatives of vectors \mathbf{r}_A and \mathbf{r}_B with respect to time give the velocities of points A and B . Thus we find that

$$\mathbf{v}_A = \mathbf{v}_B,$$

i.e., at any instant the velocities of points A and B are equal in magnitude and direction.

Again, differentiating both sides of the equation with respect to time, we obtain

$$\frac{d\mathbf{v}_A}{dt} = \frac{d\mathbf{v}_B}{dt} \quad \text{or} \quad \mathbf{w}_A = \mathbf{w}_B.$$

Hence, at any instant the accelerations of A and B are equal in magnitude and direction.

As points A and B are arbitrary, it follows that the paths and the velocities and accelerations of all the points of a body at any instant are the same, which proves the theorem.

It follows from the theorem that the translatory motion of a rigid body is fully described by the motion of any point belonging to it. Thus, the analysis of translatory motion of a rigid body is reduced to the methods of particle kinematics examined before.

The common velocity \mathbf{v} of all the points of a body in translatory motion is called the *velocity of translation*, and the common acceleration \mathbf{w} is called the *acceleration of translation*.

Vectors \mathbf{v} and \mathbf{w} can, obviously, be shown as applied at any point of the body.

It should be noted that the notions of velocity and acceleration of a body make sense only when translation is considered. In all other cases, as we shall see later, the points of a body have different velocities and accelerations and the expressions "velocity of a body" or "acceleration of a body" are meaningless.

Fig. 162.

74. Rotational Motion of a Rigid Body. Angular Velocity and Angular Acceleration.

*Rotation of a rigid body is such a motion in which there are always two points of the body (or body extended) which remain motionless (see Fig. 162). The line AB through these fixed points is called the *axis of rotation*.*

Since the distance between the points of a rigid body does not change, it is evident that in rotational motion all points of the body on the axis of rotation are motionless, while all the other points of the body describe circular paths the planes of which are perpendicular to the axis of rotation and the centres of which lie on it (this is another definition of rotational motion)*.

* A body may rotate about an axis without any point of it belonging to that axis, e.g., the rotation of a wheel on an axle or the rotation of a person riding a merry-go-round.

To determine the position of a rotating body, let us pass two planes through the axis of rotation Az (Fig. 162): plane I , which is fixed, and plane II through the rotating body and rotating with it. The position of the body at any instant will be fully specified by the angle φ between the two planes, taken with the appropriate sign, which we shall call *the angle of rotation* of the body. We shall consider the angle positive if it is laid off counterclockwise from the fixed plane by an observer looking from the positive end of axis Az , and negative if it is laid off clockwise. Angle φ is always measured in *radians*.

The position of a body at any instant is completely specified if we know the angle φ as a function of time t , i.e.,

$$\varphi = f(t). \quad (36)$$

Eq. (36) describes the *rotational motion of a rigid body*.

The principal kinematic characteristics of the rotation of a rigid body are its angular velocity ω and angular acceleration ϵ .

If in an interval of time $\Delta t = t_1 - t$ a body turns through an angle $\Delta\varphi = \varphi_1 - \varphi$, the average angular velocity of the body in the given time interval is

$$\omega_{av} = \frac{\Delta\varphi}{\Delta t}.$$

The angular velocity of a body at a given time t is the value towards which ω_{av} tends when the time interval Δt tends to zero:

$$\omega = \lim_{\Delta t \rightarrow 0} \frac{\Delta\varphi}{\Delta t} \quad \text{or} \quad \omega = \frac{d\varphi}{dt}. \quad (37)$$

Thus the *angular velocity of a body at a given time is equal in magnitude to the first derivative of the angle of rotation with respect to time*. Eq. (37) also shows that the value of ω is equal to the ratio of the infinitesimal angle of rotation $d\varphi$ to the corresponding time interval dt . The sign of ω specifies the direction of the rotation. It will be noticed that $\omega > 0$ when the rotation is counterclockwise, and $\omega < 0$ when the rotation is clockwise. The dimension of angular velocity, if the time is measured in seconds, is

$$[\omega] = \frac{\text{radian}}{\text{sec}} = \text{sec}^{-1},$$

as the radian is a dimensionless unit.

The angular velocity of a body can be denoted by a vector of magnitude $\omega = \frac{d\varphi}{dt}$ along the axis of rotation of the body in the direction from which the rotation is seen as counterclockwise

(see Fig. 163). Such a vector simultaneously gives the magnitude of the angular velocity, the axis of rotation, and the sense of rotation about that axis.

Angular acceleration characterises the time rate of change of the angular velocity of a rotating body.

If in a time interval $\Delta t = t_1 - t$ the change of angular velocity of a body is $\Delta\omega = \omega_1 - \omega$, the average angular acceleration of the body in that interval of time is

$$\varepsilon_{av} = \frac{\Delta\omega}{\Delta t}.$$

The angular acceleration at a given time t is the value towards which ε_{av} tends when the time interval Δt tends to zero.

Thus,

$$\varepsilon = \lim_{\Delta t \rightarrow 0} \frac{\Delta\omega}{\Delta t} = \frac{d\omega}{dt},$$

or, taking into account Eq. (37),

$$\varepsilon = \frac{d\omega}{dt} = \frac{d^2\varphi}{dt^2}. \quad (38)$$

Fig. 163.

Thus, the angular acceleration of a body at a given time is equal in magnitude to the first derivative of the angular velocity, or the second derivative of the angular displacement, of the body with respect to time. The dimension of angular acceleration is $[\varepsilon] = \text{sec}^{-2}$.

If the angular velocity increases in magnitude, the rotation is *accelerated*, if it decreases, the rotation is *retarded*. It will be readily noticed that the rotation is accelerated when ω and ε are of the same sign, and retarded when they are of different sign.

By analogy with angular velocity, the angular acceleration of a body can be denoted by a vector ε along the axis of rotation. The direction of ε coincides with that of ω when the rotation is accelerated (Fig. 163a), and is of opposite sense when the rotation is retarded (Fig. 163b).

75. Uniform and Uniformly Variable Rotation. If the angular velocity of a rotating body does not change ($\omega = \text{const.}$), the rotation is said to be *uniform*. Let us develop the equation of uniform rotation. We have from Eq. (37) $d\varphi = \omega dt$. Hence, assuming that at the initial moment $t=0$, angle $\varphi=0$, and integrating the left-hand member from 0 to φ and the right-hand member from 0 to t , we obtain

$$\varphi = \omega t. \quad (39)$$

It follows from Eq. (39) that in uniform rotation

$$\omega = \frac{\varphi}{t}. \quad (40)$$

In engineering, the velocity of uniform rotation is often expressed as the number of revolutions per minute, viz. n rpm*.

Let us establish the relation between n rpm and ω sec⁻¹. A complete revolution turns a body through an angle of 2π , and n revolutions takes it through an angle $2\pi n$. If the duration of this rotation is $t = 1$ min = 60 sec, then from Eq. (40) we have

$$\omega = \frac{2\pi n}{60} \approx 0.1 n. \quad (41)$$

If the angular acceleration of a body does not change during the rotation ($\varepsilon = \text{const.}$), the rotation is said to be *uniformly variable*. Let us develop the equation of uniformly variable rotation, assuming that at the initial instant $t = 0$, angle $\varphi = 0$ and that the angular velocity $\omega = \omega_0$ (where ω_0 is the initial angular velocity).

From Eq. (38) we have $d\omega = \varepsilon dt$. Integrating the left-hand member over the interval ω_0 to ω and the right-hand member from 0 to t , we obtain

$$\omega = \omega_0 + \varepsilon t. \quad (42)$$

Let us write Eq. (42) in the form

$$\frac{d\varphi}{dt} = \omega_0 + \varepsilon t \quad \text{or} \quad d\varphi = \omega_0 dt + \varepsilon t dt.$$

Integrating again, we obtain the equation of uniformly variable rotation.

$$\varphi = \omega_0 t + \varepsilon \frac{t^2}{2}. \quad (43)$$

The angular velocity ω of this rotation is given by Eq. (42). If ω and ε have the same sign, the rotation is uniformly accelerated, if they have opposite signs, it is uniformly retarded.

In conclusion, mention should be made of the analogy between the equations of rectilinear motion of a particle and the equations of rotational motion of a rigid body. It will be noticed that all the equations developed in Chapter 9 turn into the equations of this section if instead of x , v , and w we substitute φ , ω and ε , respectively.

* It should be noted that n is not an angle but angular velocity.

76. Velocities and Accelerations of the Points of a Rotating Body. Having established in the previous sections the characteristics of the motion of bodies as a whole, let us now investigate the motions of individual points of bodies.

Consider a point M of a rigid body at a distance h from the axis of rotation Az (Fig. 162). When the body rotates, point M describes a circle of radius h in a plane perpendicular to the axis of rotation with its centre C on that axis. If in time dt the body makes an infinitesimal displacement through angle $d\varphi$, point M will have made a very small displacement $ds = h d\varphi$ along its path. The velocity of the point is the ratio of ds to dt , i.e.,

$$v = \frac{ds}{dt} = h \frac{d\varphi}{dt},$$

or

$$v = h\omega. \quad (44)$$

This velocity v is called the *linear*, or *circular*, velocity of the point M (not to be confused with its angular velocity).

Thus, *the linear velocity of a point belonging to a rotating body is equal to the product of the angular velocity of that body and the distance of the point from the axis of rotation.* The linear velocity is tangent to the circle described by point M , or perpendicular to the plane through the axis of rotation and the point M .

Fig. 164.

As the value of ω at any given instant is the same for all points of the body, it follows from Eq. (44) that the lin-

ear velocity of any point of a rotating body is proportional to its distance from the axis of rotation (Fig. 164).

In order to determine the acceleration of point M we apply equations

$$\omega_\tau = \frac{dv}{dt}, \quad \omega_n = \frac{v^2}{\rho}.$$

In our case, $\rho = h$. Substituting the expression for v from Eq. (44), we obtain

$$\omega_\tau = h \frac{d\omega}{dt}, \quad \omega_n = \frac{h^2 \omega^2}{h},$$

and finally

$$\omega_\tau = h\varepsilon, \quad \omega_n = h\omega^2. \quad (45)$$

The tangential acceleration ω_τ is tangent to the path (in the direction of the rotation if it is accelerated and in the reverse

direction if it is retarded); the normal acceleration ω_n is always directed along the radius h towards the axis of rotation (Fig. 165).

The total acceleration of point M is

$$w = \sqrt{w_r^2 + w_n^2} = \sqrt{h^2 \varepsilon^2 + h^2 \omega^4},$$

or

$$w = h \sqrt{\varepsilon^2 + \omega^4}. \quad (46)$$

The inclination of the vector of total acceleration to the radius of the circle described by the point is specified by the angle μ given by the equation

$$\tan \mu = \frac{|\omega_r|}{\omega_n}.$$

Substituting the expressions of ω_r and ω_n from Eqs. (45), we obtain

$$\tan \mu = \frac{|\varepsilon|}{\omega^2}. \quad (47)$$

Fig. 165.

Since at any given instant ε and ω are each the same for all the points of the body, it follows from Eqs. (46) and (47) that the accelerations of all the points of a rotating rigid body are proportional to their distances from the axis of rotation and make the same angle μ with the radii of the circles described by them (Fig. 166).

Eqs. (44)-(47) make it possible to determine the velocity and acceleration of any point of a body if the equation of rotation of the body and the distance of the given point from the axis of rotation are known. With these formulas, knowing the motion of any single point of a body, it is possible to determine the motion of any other point and the characteristics of the motion of the body as a whole.

Fig. 166.

Problem 62. A shaft rotating with a speed of $n = 90$ rpm decelerates uniformly when the motor is switched off and stops in $t_s = 40$ sec. Determine the number of revolutions made by the shaft in this time.

Solution. As the rotation is uniformly retarded,

$$\varphi = \omega_0 t + \varepsilon \frac{t^2}{2}, \quad (a)$$

$$\omega = \omega_0 + \varepsilon t. \quad (b)$$

The initial angular velocity of the uniformly retarded rotation is that which the shaft had before the motor was switched off. Hence,

$$\omega_0 = \frac{\pi n}{30}.$$

At the instant $t = t_1$, when the shaft stopped, its angular velocity was $\omega_1 = 0$. Substituting these values into equation (b), we obtain:

$$0 = \frac{\pi n}{30} - \varepsilon t_1 \quad \text{and} \quad \varepsilon = -\frac{\pi n}{30 t_1}.$$

If we denote as N the number of revolutions of the shaft in time t_1 (not to be confused with n , which is the angular velocity!), the angle of rotation in that time will be $\varphi_1 = 2\pi N$. Substituting the values of ε and φ_1 in equation (a), we obtain

$$2\pi N = \frac{\pi n}{30} t_1 - \frac{\pi n}{60} t_1 = \frac{\pi n}{60} t_1,$$

whence

$$N = \frac{n t_1}{120} = 30 \text{ revolutions.}$$

Problem 63. A flywheel of radius $R = 1.2 \text{ m}$ rotates uniformly, making $n = 90 \text{ rpm}$. Determine the linear velocity and acceleration of a point on the rim of the flywheel.

Solution. The linear velocity of such a point is $v = R\omega$, where the angular velocity ω must be expressed in radians per second. In our case

$$\omega = \frac{\pi n}{30} = 3\pi \text{ sec}^{-1}.$$

Hence,

$$v = \frac{\pi n}{30} R \approx 11.3 \text{ m/sec.}$$

As $\omega = \text{const.}$, $\varepsilon = 0$, and consequently

$$a = a_n = R\omega^2 = \frac{\pi^2 n^2}{900} R \approx 106.6 \text{ m/sec}^2.$$

The acceleration is directed towards the axis of rotation.

Problem 64. The equation of the motion of an accelerated flywheel is

$$\varphi = \frac{9}{32} t^3.$$

Determine the linear velocity and acceleration of a point lying at a distance $h = 0.8 \text{ m}$ from the axis of rotation at the instant when its tangential and normal accelerations are equal.

Solution. We determine the angular velocity and angular acceleration of the flywheel:

$$\omega = \frac{d\varphi}{dt} = \frac{27}{32} t^2, \quad \varepsilon = \frac{d\omega}{dt} = \frac{27}{16} t.$$

The formulas for the tangential and normal acceleration of the point are $a_\tau = h\varepsilon$, and $a_n = h\omega^2$.

Denote the instant when $\omega_2 = \omega_n$ by the symbol t_1 . Obviously, at that instant $\varepsilon_1 = \omega_1^2$, or

$$\frac{27}{16} t_1 = \left(\frac{27}{32} \right)^2 t_1^3,$$

whence

$$t_1^2 = \frac{64}{27} \quad \text{and} \quad t_1 = \frac{4}{3} \text{ sec.}$$

Substituting this value of t_1 in the expressions for ω and ε , we find that at time t_1

$$\omega_1 = \frac{3}{2} \text{ sec}^{-1}, \quad \varepsilon_1 = \frac{9}{4} \text{ sec}^{-2}.$$

The required values are thus

$$v_1 = h\omega_1 = 1.2 \text{ m/sec}; \quad \omega_1 = h\sqrt{\varepsilon_1^2 + \omega_1^4} = 1.8\sqrt{2} \approx 2.51 \text{ m/sec}^2.$$

Vector ω_1 makes 45° with the radius h .

Problem 65. The weight B in Fig. 167 rotates a shaft of radius r with gear 1 of radius r_1 mounted on it. The weight starts moving from rest with a constant acceleration a . Develop the equation of rotation of the gear 2 of radius r_2 which is meshed with gear 1.

Solution. As the initial velocity of the weight is zero, its velocity v_B at any instant t is at ($v_B = at$). All the points on the surface of the shaft have the same velocity. At the same time, their velocity is $\omega_1 r$, where ω_1 is the angular velocity of both the shaft and gear 1. Consequently,

$$\omega_1 r = at, \quad \omega_1 = \frac{at}{r}.$$

Fig. 167.

Now let us determine ω_2 . As at point C , where the gears mesh, the linear velocity of both gears must be the same, we have $v_C = \omega_1 r_1 = \omega_2 r_2$, whence

$$\omega_2 = \frac{r_1}{r_2} \omega_1 = \frac{r_1 a}{r_2 r} t.$$

Thus, the angular velocity of gear 2 increases in proportion to time. Since $\omega_2 = \frac{d\varphi_2}{dt}$, where φ_2 is the angle of rotation of gear 2, we have

$$d\varphi_2 = \frac{r_1 a}{r_2 r} t dt,$$

from which, integrating both sides and assuming angle $\varphi_2 = 0$ at time $t = 0$, we obtain the equation of uniformly accelerated rotation of gear 2 in the form

$$\varphi_2 = \frac{r_1 a}{2 r r_2} t^2.$$

Chapter 12

PLANE MOTION OF A RIGID BODY

77. Equations of Plane Motion. Resolution of Motion Into Translation and Rotation. *Plane motion of a rigid body is such motion in which all its points move parallel to a fixed plane P (Fig. 168). Many machine parts have plane motion, for example, a wheel running on a straight track or the connecting rod of a reciprocating engine. Rotation is, in fact, a special case of plane motion.*

Fig. 168.

In plane motion, all the points of a body belonging to a line MM' (see Fig. 168) normal to plane P move in the same way. Therefore, in investigating plane motion it is sufficient to investigate the motion of a section S of that body produced by passing any plane Oxy through it parallel to the

fixed plane P . In this book we shall always take the plane Oxy parallel to the page and represent a body by its section S .

The position of section S in plane Oxy is completely specified by the position of any point A of the section, i.e., by its coordinates x_A and y_A (Fig. 169), and the angle φ between an arbitrary line AB in section S and the x axis.

Fig. 169

Fig. 170.

The point A chosen to define the position of section S is called the *pole*. As the body moves, the quantities x_A , y_A , and φ are changing and the motion of the body, i.e., its position in space at any moment of time, is completely specified if we know

$$x_A = f_1(t); \quad y_A = f_2(t); \quad \varphi = f_3(t). \quad (48)$$

Eqs. (48) are the *equations of plane motion of a rigid body*.

Consider the successive positions I and II of the section S of a moving body at instants t_1 and $t_2 = t_1 + \Delta t$ (Fig. 170). It will

be observed that the following method can be employed to move section S , and with it the whole body, from position I to position II . Let us first translate the body so that pole A occupies position A_2 (line A_1B_1 occupies position A_2B_1') and then turn the section about pole A_2 through angle $\Delta\varphi_1$. In the same way we can move the body from position II to some new position III , etc. We conclude that *the plane motion of a rigid body is a combination of a translation, in which all the points move in the same way as the pole A , and of a rotation about that pole**.

The translatory component of plane motion can, evidently, be described by the first two of Eqs. (48), and the rotational component by the third.

The principal kinematic characteristics of this type of motion are the velocity and acceleration of translation, equal each to the velocity and acceleration of the pole ($v_{\text{trans}} = v_A$, $w_{\text{trans}} = w_A$), and the angular velocity ω and angular acceleration ε of the rotation about the pole. The values of these characteristics can be found for any time t from Eqs. (48).

Fig. 171.

In analysing plane motion, we are free to choose any point of the body as the pole. Had we chosen some point C instead of A (Fig. 171), the characteristics of the translatory component of the motion would have been different, for in the general case $v_C \neq v_A$ and $w_C \neq w_A$ (otherwise the motion would be that of pure translation). The characteristics of the rotational component of the motion ω and ε remain, however, the same. For, drawing CD parallel to AB to determine the rotation about pole C (which is always possible, because AB and CD are arbitrary), we obtain that at any instant angle $\varphi_1 = \varphi$, i.e., the equations of rotation about poles A and C are the same. Hence,

$$\frac{d\varphi_1}{dt} = \frac{d\varphi}{dt}, \quad \frac{d^2\varphi_1}{dt^2} = \frac{d^2\varphi}{dt^2},$$

or

$$\omega_1 = \omega, \quad \varepsilon_1 = \varepsilon.$$

This result can also be explained as follows. Consider again the displacement of the body from position I to position II (see Fig. 170), taking point B as the pole. Then, by translating the

* The rotation takes place about an axis perpendicular to the plane P through the pole A . For the sake of brevity, however, we shall speak simply of rotation about the pole A .

body together with the pole, we bring it from position B_1 into position B_2 (line B_1A_1 occupying the position $B_2A'_1$). Now, rotating the section S about pole B_2 through an angle $\Delta\varphi_2$, we bring the body into position II. It will be readily noticed that in this case the translatory displacement B_1B_2 differs from displacement A_1A_2 , when point A was taken as the pole, while the angle of rotation $\Delta\varphi_2 = \Delta\varphi_1$ (as $B_2A'_1 \parallel A_2B'_1$). Consequently, the rotational component of the motion is the same for any position of the pole.

78. Determination of the Paths of the Points of a Body. Let us now investigate the motion of individual points of a rigid body, i.e., determine their paths, velocities and accelerations. For this, as has been shown, it is sufficient to analyse the motion of the points lying in section S . We shall begin with the determination of the paths.

Fig. 172.

Consider point M of a body whose position in section S is specified by its distance $b = AM$ from the pole A and the angle $BAM = \alpha$ (Fig. 172). If the motion of the body is described by Eqs. (48),

the x and y coordinates of point M in the system Oxy will be

$$\begin{aligned} x &= x_A + b \cos(\varphi + \alpha), \\ y &= y_A + b \sin(\varphi + \alpha), \end{aligned} \quad (49)$$

where x_A , y_A , φ are the functions of time t given by the Eqs. (48).

Eqs. (49) describe the motion of point M in plane Oxy and at the same time give the equation of the point's path in parametric form. The usual equation of the path can be obtained by eliminating time t from Eqs. (49).

If the body under consideration is part of a mechanism, the path of any point M of the body can be determined by expressing the coordinates of the point in terms of a parameter specifying the position of the mechanism and then eliminating that parameter. In this case the equations of motion (48) are not necessary.

Problem 66. Blocks A and B , to which the rule of an ellipsograph is attached, slide in mutually perpendicular slots (Fig. 173). Assuming $AB = l$, determine the path of point M of the rule.

Solution. Taking point A as the pole, let us specify the position of M on the rule in terms of segment $AM = b$. The position of the rule itself is specified by angle φ . Hence, for coordinates x and y of point M we obtain

$$x = (b - l) \cos \varphi, \quad y = b \sin \varphi.$$

Eliminating parameter φ , we find that the path of the point (independent of the equation of motion of the rule) is an ellipse:

$$\frac{x^2}{(b-l)^2} + \frac{y^2}{b^2} = 1,$$

with semiaxes $a = |b-l|$ and b and centre at O .

By adjusting the distances l and b , we can trace with a pencil at M an ellipse with any given semiaxes not longer than the rule, which is why the instrument is called an ellipsograph.

Fig. 173.

79. Determination of the Velocity of Any Point of a Body.

Plane motion of a rigid body is a combination of a translation in which all points of the body move with the velocity of the pole v_A , and a rotation about that pole. Let us show that the velocity of any point M of the body is the geometric sum of its velocities for each component of the motion.

The position of a point M in section S of the body is specified with reference to the coordinate axes Oxy by the radius vector $r = r_A + r'$ (Fig. 174), where vector $r' = \overline{AM}$. Then,

$$v_M = \frac{dr}{dt} = \frac{dr_A}{dt} + \frac{dr'}{dt}.$$

In this equation $\frac{dr_A}{dt} = v_A$, i.e., it is equal to the velocity of the pole A ; the quantity $\frac{dr'}{dt}$ is equal to the velocity v_{MA} of point M

at $r_A = \text{const.}$, i.e., when A is fixed or, in other words, when the body rotates about the pole A . It thus follows from the preceding equation that

$$v_M = v_A + v_{MA}. \quad (50)$$

The velocity of rotation v_{MA} of point M about pole A is (§ 76)

$$v_{MA} = \omega MA \quad (v_{MA} \perp \overline{MA}), \quad (51)$$

where ω is the angular velocity of the rotation of the body.

Thus, the velocity of any point M of a body is the geometric sum of the velocity of any other point A taken as the pole and the velocity of rotation of the point M about the pole. The magnitude

Fig. 174.

and direction of the velocity \mathbf{v}_M are found by constructing a parallelogram (Fig. 175).

Problem 67. Determine the velocity of a point M on the rim of a wheel of radius R (Fig. 176) running without slipping along a straight rail, if the velocity of the centre C of the wheel is v_C , and angle $DKM = \alpha$.

Fig. 175.

Fig. 176.

Solution. Taking point C , whose velocity is known, as the pole, we find that $\mathbf{v}_M = \mathbf{v}_C + \mathbf{v}_{MC}$, where $\mathbf{v}_{MC} \perp \overline{CM}$, and in magnitude $v_{MC} = \omega MC = \omega R$. The magnitude of the angular velocity is determined from the condition that point K of the wheel does not slip and, consequently, at the given moment $v_K = 0$. On the other hand, just as for point M , $\mathbf{v}_K = \mathbf{v}_C + \mathbf{v}_{KC}$, where $v_{KC} = \omega KC = \omega R$. For point K , \mathbf{v}_{KC} and \mathbf{v}_C are collinear, therefore, at $v_K = 0$, $v_{KC} = v_C$, whence $\omega = \frac{v_C}{R}$. Thus we find that

$$v_{MC} = \omega R = v_C.$$

The parallelogram constructed with vectors \mathbf{v}_{MC} and \mathbf{v}_C as its sides is a rhombus. But the angle between \mathbf{v}_C and \mathbf{v}_{MC} is equal to angle β , as the sides of these angles are mutually perpendicular. On the other hand, angle $\beta = 2\alpha$, as a central angle subtended by the same arc as the inscribed angle α . Hence, by virtue of the properties of a rhombus, the angles between \mathbf{v}_C and \mathbf{v}_M and between \mathbf{v}_{MC} and \mathbf{v}_M are also equal to α . Finally, as the diagonals of a rhombus are mutually perpendicular, we obtain

$$v_M = 2v_C \cos \alpha \quad \text{and} \quad \mathbf{v}_M \perp \overline{KM}.$$

The computations, we see, were rather cumbersome. Further on we shall discuss methods which make it possible to solve such problems much simpler (see Problem 69).

80. Theorem of the Projections of the Velocities of Two Points of a Body. The use of Eq. (50) to determine the velocities of the points of a body usually leads to involved computations (cf. Problem 67). However, we can evolve from Eq. (50) several simpler and more convenient methods of determining the velocity of any point of a body.

One of these methods is given by the theorem: *The projections of the velocities of two points of a rigid body on the straight line joining those points are equal.*

Consider any two points A and B of a body (Fig. 177). Taking point A as the pole, we have from Eq. (50) $\mathbf{v}_B = \mathbf{v}_A + \mathbf{v}_{BA}$. Projecting both members of the equation on AB and taking into account that vector \mathbf{v}_{BA} is perpendicular to AB , we obtain

$$v_B \cos \beta = v_A \cos \alpha, \quad (52)$$

Fig. 177.

and the theorem is proved. This result offers a simple method of determining the velocity of any point of a body if the direction of motion of that point and the velocity of any other point of the same body are known.

Problem 68. Determine the relation between the velocities of points A and B of the ellipsograph rule in Fig. 173 if angle φ is given.

Solution. The directions of the velocities of points A and B are known. Hence, projecting vectors \mathbf{v}_A and \mathbf{v}_B on AB and applying the above theorem, we obtain

$$v_A \cos \varphi = v_B \cos (90^\circ - \varphi),$$

whence

$$v_A = v_B \tan \varphi.$$

81. Determination of the Velocity of Any Point of a Body Using the Instantaneous Centre of Zero Velocity.

Another simple and visual method of determining the velocity of any point of a body performing plane motion is based on the concept of instantaneous centre of zero velocity. *The instantaneous centre of zero velocity is a point belonging to the section S of a body or its extension which at the given instant is momentarily at rest.*

Fig. 178.

It will be readily noticed that if a body is in non-translatory motion, such a point, and only one point, always exists at any instant t . Let points A and B in section S of a body (Fig. 178) have, at time t , non-parallel velocities \mathbf{v}_A and \mathbf{v}_B . Then point P at the intersection of perpendiculars Aa to vector \mathbf{v}_A and Bb to vector \mathbf{v}_B will be the instantaneous centre of zero velocity, as $\mathbf{v}_P = 0$. For, if we assumed that $\mathbf{v}_P \neq 0$, then, by the theorem of the projections of the velocities of the points of a body, vector \mathbf{v}_P

would have to be simultaneously perpendicular to AP (as $\mathbf{v}_A \perp AP$) and to BP (as $\mathbf{v}_B \perp BP$), which is impossible. It also follows from the theorem that, at the given instant, no other point of section S can have zero velocity (e.g., for point a , the projection of \mathbf{v}_B on Ba is not zero and consequently $\mathbf{v}_a \neq 0$).

If, now, we take a point P as the pole at time t , the velocity of point A will, by Eq. (50), be

$$\mathbf{v}_A = \mathbf{v}_P + \mathbf{v}_{AP} = \mathbf{v}_{AP},$$

as $\mathbf{v}_P = 0$. The same result can be obtained for any other point of the body. Thus, *the velocity of any point of a body lying in section S is equal to the velocity of its rotation about the instantaneous centre of zero velocity P* . From Eqs. (51) we have

$$\begin{aligned} v_A &= \omega PA, & (\mathbf{v}_A \perp \overline{PA}), \\ v_B &= \omega PB, & (\mathbf{v}_B \perp \overline{PB}), \text{ etc.} \end{aligned} \quad (53)$$

It also follows from Eqs. (53) that

$$\frac{v_A}{PA} = \frac{v_B}{PB}, \quad (54)$$

i.e., that *the velocity of any point of a body is proportional to its distance from the instantaneous centre of zero velocity*.

These results lead to the following conclusions:

1) *To determine the instantaneous centre of zero velocity, it is sufficient to know the directions of the velocities \mathbf{v}_A and \mathbf{v}_B of any two points A and B of a section of a body (or their paths); the instantaneous centre of zero velocity lies at the intersection of the perpendiculars erected from points A and B to their respective velocities, or to the tangents to their paths.*

2) *To determine the velocity of any point of a body, it is necessary to know the magnitude and direction of the velocity of any point A of that body and the direction of the velocity of another point B of the same body. Then, by erecting from points A and B perpendiculars to \mathbf{v}_A and \mathbf{v}_B , we obtain the instantaneous centre of zero velocity P and, from the direction of \mathbf{v}_A , the sense of rotation of the body. Next, knowing v_A , we can find from Eq. (54) the velocity v_M of any point M of the body. Vector \mathbf{v}_M is perpendicular to \overline{PM} in the direction of the rotation.*

3) *The angular velocity of a body, as can be seen from Eqs. (53), is at any given instant equal to the ratio of the velocity of any point belonging to the section S to its distance from the instantaneous centre of zero velocity P :*

$$\omega = \frac{v_A}{PA}. \quad (55)$$

Let us evolve another expression for ω . It follows from Eqs. (50) and (51) that $v_{AB} = |\mathbf{v}_A - \mathbf{v}_B|$ and $v_{AB} = \omega \cdot AB$, whence

$$\omega = \frac{|\mathbf{v}_A - \mathbf{v}_B|}{AB} = \frac{|\mathbf{v}_A + (-\mathbf{v}_B)|}{AB}. \quad (56)$$

Eqs. (55) and (56) give the same quantity as, from § 77, it follows that the rotation of the section S about either point A or point P takes place with the same angular velocity ω .

Example. The directions of the velocities of points A and B of the ellipsograph rule in Fig. 179 are known. Erecting perpendiculars to them, we obtain the instantaneous centre of zero velocity P of the rule.

Knowing P , we obtain from the proportion $\frac{v_A}{PA} = \frac{v_B}{PB}$, $v_A = v_B \frac{PA}{PB} = v_B \tan \varphi$, i.e., the same result as in Problem 68. Similarly, we obtain for point M , $v_M = v_B \frac{PM}{PB}$. The length of PM can be calculated if we know AB , AM , and angle φ . The direction of vector \mathbf{v}_M is shown in the diagram ($\mathbf{v}_M \perp PM$).

From Eqs. (55) and (56) we find the angular velocity of the rule:

$$\omega = \frac{v_B}{PB} \quad \text{or} \quad \omega = \frac{|\mathbf{v}_B - \mathbf{v}_A|}{AB}.$$

It is easy to verify that both equations give the same answer.

Fig. 179.

Let us consider some special cases of the instantaneous centre of zero velocity.

a) If plane motion is performed by a cylinder rolling without slipping along a fixed cylindrical surface, the point of contact P (Fig. 180) is momentarily at rest and, consequently, is the instantaneous centre of zero velocity ($v_P = 0$ because, if there is no slipping, the contacting points of both bodies must have the same velocity, and the second body is motionless). An example of such motion is that of a wheel running on a rail.

Fig. 180.

b) If the velocities of points A and B of the body in Fig. 181 are parallel to each other, and AB is not perpendicular to \mathbf{v}_A , the instantaneous centre of zero velocity lies in infinity, and the velocities of all points are parallel to \mathbf{v}_A . From the theorem of the projections of velocities it follows that $v_A \cos \alpha = v_B \cos \beta$, i.e., $v_B = v_A$; the result is the same for all other points of the body. Consequently, in this case the velocities of

all points of the body are equal in magnitude and direction at every instant, i.e., the *instantaneous distribution of the velocities of the body is that of translation* (this state of motion is also called *instantaneous translation*). It will be found from Eq. (56) that the angular velocity of the body at the given instant is zero.

c) If the velocities of points A and B are parallel, and AB is perpendicular to \mathbf{v}_A , the instantaneous centre of zero velocity

Fig. 181.

Fig. 182.

P can be located by the construction shown in Fig. 182. The validity of this construction follows from the proportion (54). In this case, unlike the previous ones, we also have to know the magnitudes of velocities v_A and v_B to locate the instantaneous centre of zero velocity P .

The above shows that in plane motion the velocities of the points of a body are distributed at any given instant as if the body were rotating about an axis Pz , perpendicular to the section S through point P . This line is called the *instantaneous axis of rotation* of the body. Unlike a fixed axis of rotation, the instantaneous axis continually changes its position. Plane motion is the result of a series of consecutive infinitesimal rotations about the instantaneous axis of rotation.

82. Solution of Problems*. In order to determine the kinematic characteristics of motion (the angular velocity of a body or the velocities of its points) we must know the magnitude and direction of the velocity of an arbitrary point of the body and the direction of the velocity of any other point of that body (with the exception of cases a) and b) discussed in § 81). The solution of any problem begins with the determination of these characteristics from the statement of the problem.

The mechanism whose motion is being investigated should be drawn in the position for which the corresponding characteristics are being determined. In solving a problem, it should be remembered that the concept of instantaneous centre of zero velocity applies to a given rigid body. *In mechanisms consisting of several bodies, every body performing non-translatory motion has at any*

* An example of the methods of problem solution discussed here can be found in § 96, Problem 90.

instant its own instantaneous centre of zero velocity and its own angular velocity.

Problem 69. Determine the velocity of point M on the rim of the rolling wheel in Problem 67 by introducing the instantaneous centre of zero velocity.

Solution. The point of contact P of the wheel (Fig. 183) is the instantaneous centre of zero velocity, as $v_P = 0$. Consequently, $\mathbf{v}_M \perp PM$. As the right angle PMD rests on the diameter, the velocity vector \mathbf{v}_M of any point of the rim passes through point D . Writing the proportion

$$\frac{v_M}{PM} = \frac{v_C}{PC}$$

and noting that $PC = R$ and $PM = 2R \cos \alpha$, we find

$$v_M = 2v_C \cos \alpha.$$

The further point M is from P , the greater its velocity. The upper end D of the vertical diameter has the maximum velocity $v_D = 2v_C$. The angular velocity of the wheel, from Eq. (55), is

$$\omega = \frac{v_C}{PC} = \frac{v_C}{R}.$$

Fig. 183.

The velocities are similarly distributed for all cases of a wheel or gear rolling along a cylindrical surface (see Fig. 180).

Problem 70. Determine the velocity of the centre C of the free pulley of radius r in Fig. 184 and its angular velocity ω if load A is moving up with a velocity v_A and load B is moving down with a velocity v_B . The thread does not slip and all its sections are vertical.

Fig. 184.

Solution. As the thread does not slip on the free pulley, the velocities of points a and b of the pulley are equal in magnitude to the velocities of the loads, i.e., $v_a = v_A$ and $v_b = v_B$. Knowing the velocities of points a and b and assuming for convenience that $v_B > v_A$, we can determine the position of the instantaneous centre of zero velocity P of the free pulley by the same method as in Fig. 182. The velocity of the centre of the pulley C is denoted by the vector \mathbf{v}_C . From Eq. (56) we develop the equations

$$\omega = \frac{|\mathbf{v}_b + (-\mathbf{v}_a)|}{ab} \quad \omega = \frac{|\mathbf{v}_b - \mathbf{v}_C|}{bC},$$

whence, as $ab = 2r$ and $bC = r$, we obtain

$$\omega = \frac{v_B + v_A}{2r}, \quad v_C = \frac{v_B - v_A}{2}.$$

At $v_B > v_A$ the centre moves up; if $v_B < v_A$ it moves down; at $v_B = v_A$, $v_C = 0$.

The values of ω and v_C for the case of both loads lowering can be found by substituting $-v_A$ for v_A in the equations.

Problem 71. Crank OA of length r of the mechanism in Fig. 185 rotates with an angular velocity ω_{OA} . The length of the connecting rod $AB = l$. If angle φ is given, determine: 1) the velocity of block B , 2) the position of the point M on the connecting rod which has the least velocity, 3) the angular velocity ω_{AB} of the connecting rod. Also analyse the positions of the mechanism for $\varphi = 0$ and $\varphi = 90^\circ$.

Solution. It follows from the statement of the problem that the velocity of point A is $v_A = \omega_{OA}r$ perpendicular to OA , and the velocity of B is directed along BO . This data is sufficient to determine all the kinematic characteristics of the connecting rod.

Fig. 185.

1) From the theorem of the projections of velocities we have $v_A \cos \alpha = v_B \cos \beta$. Angle OAD , as a supplementary angle of triangle OAB , is equal to $\varphi + \beta$. Hence, $\alpha = 90^\circ - (\varphi + \beta)$, and

$$v_B = \omega_{OA}r \frac{\sin(\varphi + \beta)}{\cos \beta} = \omega_{OA}r (\sin \varphi + \cos \varphi \tan \beta).$$

Now eliminate angle β from the equation. From triangle OAB ,

$$\frac{\sin \beta}{r} = \frac{\sin \varphi}{l}.$$

Furthermore,

$$\tan \beta = \frac{\sin \beta}{\sqrt{1 - \sin^2 \beta}},$$

and finally

$$v_B = \omega_{OA}r \left(1 + \frac{r \cos \varphi}{\sqrt{l^2 - r^2 \sin^2 \varphi}} \right) \sin \varphi.$$

2) The instantaneous centre of zero velocity P of the connecting rod (AP is an extension of OA) is located by erecting perpendiculars from points A and B . The point with the least velocity M is that which is closest to the centre P , i.e., on the perpendicular PM to AB . Its velocity is

$$v_M = v_A \cos \alpha = \omega_{OA}r \sin(\varphi + \beta).$$

3) From Eq. (55), the angular velocity of the rod is

$$\omega_{AB} = \frac{v_A}{PA} \quad \text{or} \quad \omega_{AB} = \frac{v_B}{PB}.$$

The length PB (or PA) is calculated from the data given in the statement of the problem.

4) At angle $\varphi = 0$ (Fig. 186a), the perpendicular AB to velocity v_A and the perpendicular Bb to v_B intersect at B . Consequently, for this position point B is the instantaneous centre of velocity, and $v_B = 0$ (the "dead centre", position of the mechanism). For this position

$$\omega_{AB} = \frac{v_A}{AB} = \frac{r}{l} \omega_{OA}.$$

The distribution of the velocities along the connecting rod is shown in the diagram.

5) At angle $\varphi = 90^\circ$ (Fig. 186b), velocities v_A and v_B are parallel, and the perpendiculars to them intersect in infinity. Consequently, at that instant all the points of the rod have the same velocity v_A ; $\omega_{AB} = 0$.

Fig. 186.

Fig. 187.

Problem 72. Link OA in Fig. 187 rotates about axis O with an angular velocity ω_{OA} ; with it moves gear 1 which rolls around the fixed gear 2. The radii of the two gears are both equal to r . Hinged to gear 1 is a connecting rod BD of length l , attached to which is a rockshaft DC . Determine the angular velocity ω_{BD} of the connecting rod for the instant when it is perpendicular to link OA , if at that instant angle $BDC = 45^\circ$.

Solution. To determine ω_{BD} we must know the velocity of an arbitrary point on the connecting rod BD and the position of its instantaneous centre of zero velocity. Let us determine the velocity of point B from the fact that it also belongs to gear 1, for which the velocity is known to be $v_A = \omega_{OA} 2r$ ($v_A \perp OA$) and the instantaneous centre of zero velocity is at P_1 . Consequently, $v_B \perp PB$, and from the theorem of the projections of velocities $v_B \cos 45^\circ = v_A$, whence $v_B = v_A \sqrt{2} = 2r\omega_{OA} \sqrt{2}$.

Now we know the velocity v_B of a point of the connecting rod and the direction of velocity v_D ($v_D \perp DC$). Erecting perpendiculars to v_B and v_D , we obtain the instantaneous centre of zero velocity P_{BD} of the connecting rod. It will be readily noticed that the segment

$$BP_{BD} = l \frac{\sqrt{2}}{2},$$

whence

$$\omega_{BD} = \frac{v_B}{BP_{BD}} = 4 \frac{r}{l} \omega_{OA}.$$

It should be noted that it would be wrong to attempt to locate the instantaneous centre of zero velocity by drawing perpendiculars to vectors v_A and v_D (a characteristic mistake). Points A and D belong to different bodies, and the intersection of these perpendiculars does not locate the centre of zero velocity (compare with Problem 73).

Problem 73. A gear 1 and crank OA are mounted independently of each other on an axle O (Fig. 188). The crank rotates with an angular velocity ω_{OA} . Fixed to the connecting rod AB with its centre at A is gear 2. The crank OA

carries axis A of the gear 2, the connecting rod passes through the rocker slide C . The radii of gears 1 and 2 are both equal to r . Determine the angular velocity ω_1 of gear 1 at the instant when $OA \perp OC$, if $\angle ACO = 30^\circ$.

Solution. To determine the angular velocity of gear 1, we have to find the linear velocity of its point E . For this we make use of the fact that point E of gear 2 has the same velocity. For gear 2 we know the direction and magnitude of the velocity of point A :

$$\mathbf{v}_A \perp OA, \quad v_A = \omega_{OA} 2r.$$

Besides, we know the direction of velocity \mathbf{v}_E , but in this case this is not sufficient, as $\mathbf{v}_E \parallel \mathbf{v}_A$. Neither can the value of \mathbf{v}_E be found from the theorem of the projections of velocities, since \mathbf{v}_A and \mathbf{v}_E are perpendicular to AE .

Therefore we shall exploit the fact that, being riveted together, gear 2 and the connecting rod are actually one body for which we know the direction of the velocity of point C : vector \mathbf{v}_C is directed along CA , as at point C the rod can only slide in the rocker. By erecting perpendiculars to \mathbf{v}_A and \mathbf{v}_C , we obtain the instantaneous centre of zero velocity P of the body BAE .

From the statement of the problem, $\angle ACO = 30^\circ$, hence $\angle CPA = 30^\circ$. Therefore $AC = 2AO = 4r$, $PA = 2AC = 8r$, $PE = 7r$, and from the proportion

$$\frac{v_E}{PE} = \frac{v_A}{PA}$$

we find that $v_E = \frac{7}{8} v_A = \frac{7}{4} r \omega_{OA}$, whence

$$\omega_1 = \frac{v_E}{OE} = \frac{7}{4} \omega_{OA}.$$

83. Velocity Diagram. The velocity of any point of a body can be determined graphically by constructing a velocity diagram. A velocity diagram is a drawing in which from some centre are laid off the velocity vectors of points of a body.

Let $\mathbf{v}_A, \mathbf{v}_B, \mathbf{v}_C$ be the velocities of points A, B, C of a given body (Fig. 189a). Then the velocity diagram can be drawn by laying off to some scale from an arbitrary point O (Fig. 189b) line segments

$$\overline{Oa} = \mathbf{v}_A, \quad \overline{Ob} = \mathbf{v}_B, \quad \overline{Oc} = \mathbf{v}_C.$$

Let us establish the properties of, and the procedure for constructing, a velocity diagram. From Eqs. (50) and (51) (see § 79) we have

$$\mathbf{v}_B = \mathbf{v}_A + \mathbf{v}_{BA}, \quad (57)$$

where

$$\mathbf{v}_{BA} \perp AB \quad \text{and} \quad v_{BA} = \omega \cdot AB. \quad (57')$$

Fig. 188.

But from triangle Oab we have $\overline{Ob} = \overline{Oa} + \overline{ab}$, or $\mathbf{v}_B = \mathbf{v}_A + \overline{ab}$. Comparing this result with Eq. (57), we find that $\overline{ab} = \mathbf{v}_{BA}$. Similarly we find that $\overline{ac} = \mathbf{v}_{CA}$, etc. Then, from formulas (57'),

$$ab \perp AB, ac \perp AC, \text{ etc.} \quad (58)$$

Furthermore, it also follows from those formulas that $ab = \omega \cdot AB$, $ac = \omega \cdot AC$, etc., whence

$$\frac{ab}{AB} = \frac{ac}{AC} = \frac{bc}{BC} = \dots = \omega. \quad (58')$$

Thus, the lines joining the tips of the velocity vectors in the velocity diagram are perpendicular to the lines joining the respec-

Fig. 189.

tive points of the body and are proportional to them in magnitude; the figures denoted by the same letters in the velocity diagram and in section S of the body are similar and lie at right angles to each other.

The relations in (58) and (58') make it possible to construct a velocity diagram and to determine the velocity of any point of a body if the magnitude and direction of the velocity of any one point and the direction of the velocity of any other point of the body are known.

If a velocity diagram is available, the angular velocity is determined by formula (58').

The velocity diagram of a mechanism is constructed as a combination of the velocity diagrams of all its parts (bodies), all the vectors being laid off from a common centre O . An example of such a construction is given in Problem 74.

Problem 74. Construct a velocity diagram for the mechanism in the position shown in Fig. 190a, if velocity \mathbf{v}_A of the end of crank $O'A$ is known. The connecting link ABC is a rigid triangular lamina. Rod $O'D$ is hinged at D to the centre of rod CE ($CD = DE$).

Solution. 1) Choose a scale (e. g., 1 cm to 0.1 m) and draw the mechanism in the required position (Fig. 190a).

2) **Determination of \mathbf{v}_B .** Choose a velocity scale (e. g., 1 cm to 0.5 m/sec) and lay off from an arbitrary centre O vector $\overline{Oa} = \mathbf{v}_A$ perpendicular to $O'A$

(Fig. 190b). From the same centre lay off a line Ob parallel to v_B (velocity v_B is directed along BO'), and from point a a line $ab \perp AB$ to its intersection with Ob . Then, from Eq. (58), point b gives the tip of vector $\overline{Ob} = v_B$.

3) Determination of v_C . From point a draw a line perpendicular to AC , and from point b a line perpendicular to BC . By Eq. (58), their intersection gives point c . Joining points O and c , we obtain vector $\overline{Oc} = v_C$.

4) Determination of v_D . The direction of v_D is known ($v_D \perp O'D$). Drawing from O line Od parallel to v_D , and from point c a line perpendicular to CD , we obtain at their intersection point d . Joining O and d , we obtain vector $\overline{Od} = v_D$.

5) Determination of v_E . Point E lies on line CDE , hence, by virtue of similarity, point e on the velocity diagram must lie on cde and from Eq. (58') we obtain $cd:de = CD:DE$. As $DE = CD$, by laying off $de = cd$ along the extension of cd , we obtain point e . Joining points O and e , we obtain vector $\overline{Oe} = v_E$.

Note: The relations in (58) are valid *only* for a given rigid body. Therefore line be in the velocity diagram, for instance, will not be perpendicular to BE , as points B and E of the mechanism belong to different bodies.

From Eq. (58') we obtain the formulas for calculating the angular velocities of links ABC and CE for the given instant:

$$\omega_{ABC} = \frac{ab}{AB}, \quad \omega_{CE} = \frac{cd}{CD}.$$

Fig. 190.

In calculating the values, the different scales should be taken into account.

84. Determination of the Acceleration of Any Point of a Body. We shall demonstrate that, like velocity, the acceleration of any point M of a body in plane motion is composed of its accelerations of translation and rotation. The location of point M with respect to axes Oxy (see Fig. 174) is specified by the radius vector $r = r_A + r'$, where $r' = \overline{AM}$. Hence,

$$w_M = \frac{d^2 r}{dt^2} = \frac{d^2 r_A}{dt^2} = \frac{d^2 r'}{dt^2}.$$

In this equation the quantity $\frac{d^2 r_A}{dt^2} = w_A$ is the acceleration of the pole A , and the quantity $\frac{d^2 r'}{dt^2} = w_{MA}$ is the acceleration of point M in its rotation with the body round A (see § 79). Hence,

$$w_M = w_A + w_{MA}. \quad (59)$$

From Eqs. (46) and (47) (see § 76), the acceleration of point M in its rotation about A is

$$w_{MA} = MA \sqrt{\varepsilon^2 + \omega^4}, \quad \tan \mu = \frac{|\varepsilon|}{\omega^2}, \quad (60)$$

where ω and ϵ are the angular velocity and angular acceleration of the body*, and μ is the angle between the direction of w_{MA} and line MA .

Thus, the acceleration of any point M of a body is composed of the acceleration of any other point taken for the pole and the acceleration of the point M in its rotation together with the body about that pole. The magnitude and direction of the acceleration w_M are determined by constructing a parallelogram (Fig. 191).

However, the computation of w_M by means of the parallelogram in Fig. 191 makes the solution more difficult, as it becomes necessary first to calculate the angle μ and then the angle between vectors w_{MA} and w_A . Therefore, in problem solutions it is more convenient to replace vector w_{MA} by its tangential and normal components w_{MA}^t and w_{MA}^n , where

$$w_{MA}^t = AM \cdot \epsilon, \quad w_{MA}^n = AM \cdot \omega^2. \quad (61)$$

Vector w_{MA}^t is perpendicular to AM in the direction of the rotation, if it is accelerated, and opposite the rotation, if it is retarded; vector w_{MA}^n is always directed from point M to the pole A (Fig. 192).

Instead of Eq. (59) we obtain

$$w_M = w_A + w_{MA}^t + w_{MA}^n. \quad (62)$$

If pole A is in non-rectilinear motion, its acceleration is also composed of the tangential and normal accelerations, hence

$$w_M = w_{Az} + w_{An} + w_{MA}^t + w_{MA}^n, \quad (62')$$

the magnitudes of the latter two components being obtained from Eq. (61). Eqs. (61) and (62) should be used in solving problems, first computing the vectors in the right-hand part of the equation and then finding their geometric sum or making a graphic construction.

* In the diagram the solid circular arrow indicates the direction of ω (the direction of rotation), and the dashed arrow, the direction (the sign) of ϵ . If the motion is accelerated, both arrows point in the same direction, if the motion is retarded, they are of opposite sense.

Fig. 191.

Fig. 192.

Solution of problems. The acceleration of any point of a body at any time can be determined if the following data are known: 1) the vectors of the velocity \mathbf{v}_A and acceleration \mathbf{w}_A of any point A of the body at the prescribed time; 2) the path of some other point B of the body. In some cases, instead of the path of the second point of the body, it is sufficient to know the location of the instantaneous centre of zero velocity.

In solving problems, the body (or mechanism) should be drawn in the position for which the acceleration of the required point has to be found. The computation starts with the determination, from the conditions of the problem, of the velocity and acceleration of the point chosen as the pole. The subsequent stages of the computation are examined in detail in the sample problems below, together with necessary additional suggestions.

Problem 77 gives the graphical method of solution.

Problem 75. The centre O of a wheel of radius $R = 0.2$ m rolling along a straight rail (Fig. 193) has at a given instant a velocity $v_o = 1$ m/sec and an acceleration $w_o = 2$ m/sec². Determine the acceleration of point B lying at the end of diameter AB perpendicular to OP and the acceleration of point P coincident with the instantaneous centre of zero velocity.

Fig. 193.

Solution. 1) As \mathbf{v}_o and \mathbf{w}_o are known, we take point O for the pole.

2) Determination of ω . The point of contact P is the instantaneous centre of zero velocity;

hence the angular velocity of the wheel is

$$\omega = \frac{v_o}{PO} = \frac{v_o}{R}. \quad (a)$$

The direction of ω is determined by the direction of \mathbf{v}_o and is shown in the diagram by the solid arrow.

3) Determination of ϵ . As in equation (a) the quantity $PO = R$ is constant for any position of the wheel, by differentiating the equation with respect to time we obtain

$$\frac{d\omega}{dt} = \frac{1}{R} \frac{dv_o}{dt} \quad \text{or} \quad \epsilon = \frac{w_o}{R}. \quad (b)$$

The signs of ϵ and ω are the same, therefore the rotation of the wheel is accelerated.

It is important to remember that the value of ϵ is determined from the equation (b) only when the distance PO in equation (a) is constant.

Note: a) It should not be assumed that v_o is constant only because the given value of $v_o = 1$ m/sec. This value, stated in the conditions of the problem, is for the given instant, and it changes with time, since $w_o \neq 0$.

b) In this case $\frac{dv_o}{dt} = w_o$, as the motion of point O is rectilinear. In the general case $\frac{dv_o}{dt} = w_{or}$.

4) Determination of w_{BO}^{τ} and w_{BO}^n . As point O is our pole, from Eq. (62) we have

$$w_B = w_O + w_{BO}^{\tau} + w_{BO}^n. \quad (c)$$

In our case $BO = R$, and

$$w_{BO}^{\tau} = BO \cdot \varepsilon = w_O = 2 \text{ m/sec}^2, \quad w_{BO}^n = BO \cdot \omega^2 = \frac{v_O^2}{R} = 5 \text{ m/sec}^2. \quad (d)$$

Now draw a separate diagram for point B , showing (not necessarily to scale) the component vectors of the acceleration w_B , namely vector w_O (transferred from point O), vector w_{BO}^{τ} (in the direction of the rotation as it is accelerated), and vector w_{BO}^n (always from B towards the pole O).

5) Determination of w_B . Drawing axes Bx and By , we find that

$$w_{Bx} = w_{BO}^n - w_O = 3 \text{ m/sec}^2, \quad w_{By} = w_{BO}^{\tau} = 2 \text{ m/sec}^2,$$

whence

$$w_B = \sqrt{w_{Bx}^2 + w_{By}^2} = \sqrt{13} \approx 3.6 \text{ m/sec}^2.$$

Similarly we can easily find that the acceleration of point P is $w_P = w_{PO}^n = 5 \text{ m/sec}^2$ and is directed along PO . Thus, the acceleration of point P , whose velocity at the given instant is zero, is not zero.

Problem 76. Gear 1 of radius $r_1 = 0.3 \text{ m}$ in Fig. 194a is fixed; rolling around it is gear 2 of radius $r_2 = 0.2 \text{ m}$ mounted on link OA . The link turns about axis O and has at the given instant an angular velocity $\omega = 1 \text{ sec}^{-1}$ and an angular acceleration $\varepsilon = -4 \text{ sec}^{-2}$. Determine the acceleration of point D on the rim of the moving gear at the given instant (radius AD is perpendicular to the link).

Solution. 1) To solve the problem, consider the motion of gear 2. From the statement of the problem it is easy to determine the velocity v_A and acceleration w_A of point A of the gear, which we take as the pole.

2) Determination of v_A and w_A . Knowing ω and ε of the link, we obtain

$$\begin{aligned} v_A &= OA \cdot \omega = 0.5 \text{ m/sec}, \\ w_{A\tau} &= OA \cdot \varepsilon = -2 \text{ m/sec}^2, \\ w_{An} &= OA \cdot \omega^2 = 0.5 \text{ m/sec}^2. \end{aligned} \quad (a)$$

As the signs of v_A and $w_{A\tau}$ are different, the motion of point A from the given position is retarded. Vectors $w_{A\tau}$ and w_{An} are directed as shown in the diagram.

Fig. 194.

3) Determination of ω_2 . The point of contact P is the instantaneous centre of zero velocity of gear 2; consequently, the angular velocity of gear 2 is

$$\omega_2 = \frac{v_A}{AP} = \frac{v_A}{r_2}; \quad \omega_2 = 2.5 \text{ sec}^{-1}. \quad (b)$$

The direction of ω_2 (the direction of rotation of the gear) is determined by the direction of v_A and is indicated by the solid arrow.

4) Determination of ϵ_2 . As in the previous problem, the quantity $AP = r_2$ is constant, and consequently

$$\epsilon_2 = \frac{d\omega_2}{dt} = \frac{1}{r_2} \frac{dv_A}{dt} = \frac{w_{A\tau}}{r_2}; \quad \epsilon_2 = -10 \text{ sec}^{-2}. \quad (c)$$

As ω_2 and ϵ_2 are of different sign, the rotation of gear 2 is retarded.

5) Determination of w_{DA}^{τ} and w_{DA}^n . The acceleration of point D is found from Eq. (62'):

$$w_D = w_{A\tau} + w_{An} + w_{DA}^{\tau} + w_{DA}^n.$$

In our case $DA = r_2$, and

$$w_{DA}^{\tau} = DA \cdot \epsilon_2 = -2 \text{ m/sec}^2, \quad w_{DA}^n = DA \cdot \omega_2^2 = 1.25 \text{ m/sec}^2.$$

Now draw the component vectors of acceleration w_D (Fig. 194b), namely $w_{A\tau}$, w_{An} (transferred from point A), w_{DA}^{τ} (directed against the rotation, as it is retarded), and w_{DA}^n (from D towards the pole A).

6) Calculation of w_D . Drawing axes Dx and Dy , we find that $w_{Dx} = |w_{A\tau}| + w_{DA}^n = 3.25 \text{ m/sec}^2$, $w_{Dy} = |w_{DA}^{\tau}| - w_{An} = 1.5 \text{ m/sec}^2$, whence

$$w_D = \sqrt{w_{Dx}^2 + w_{Dy}^2} \approx 3.58 \text{ m/sec}^2.$$

The magnitude of w_D can also be obtained graphically by constructing a vector polygon with vectors $w_{A\tau}$, w_{An} , w_{DA}^{τ} , and w_{DA}^n to scale.

Problem 77. Attached to a crank OA (Fig. 195) rotating uniformly about axis O with an angular velocity $\omega_{OA} = 4 \text{ sec}^{-1}$ is a connecting rod AB hinged to a rockshaft BC . The given dimensions are: $OA = r = 0.5 \text{ m}$, $AB = 2r$,

Fig. 195.

$BC = r\sqrt{2}$. In the position shown in the diagram, $\angle OAB = 90^\circ$ and $\angle ABC = 45^\circ$. Determine for this position the acceleration of point B of the connecting rod and the angular velocity and angular acceleration of the rock-shaft BC .

Solution. The problem can be solved either graphically or analytically.

A. Graphic solution. 1) Considering the motion of the connecting rod AB , we take point A as the pole. As $\omega_{OA} = \text{const.}$, we obtain:

$$v_A = r\omega_{OA} = 2 \text{ m/sec.}, \quad \omega_A = \omega_{An} = r\omega_{OA}^2 = 8 \text{ m/sec}^2. \quad (a)$$

Draw vectors v_A and w_A on the diagram.

2) **Determination of ω_{AB} .** We know the path of point B of the connecting rod (a circle of radius BC). Hence, knowing the direction of v_B ($v_B \perp BC$), we can locate the instantaneous centre of zero velocity P of the rod. It is evident that $AP = AB = 2r$. Therefore,

$$\omega_{AB} = \frac{v_A}{AP} \quad \text{or} \quad \omega_{AB} = \frac{\omega_{OA}}{2} = 2 \text{ sec}^{-1}. \quad (b)$$

The direction of rotation is shown in the diagram.

In this case the distance AP changes with the motion of the mechanism and we cannot apply the method used in the previous two problems to determine ε_{AB} . That is why for this problem the graphic method of solution is more convenient. First determine the values of ω_{BA}^n and ω_{Bn} .

3) **Determination of ω_{BA}^n .** Knowing ω_{AB} from Eq. (61), we have

$$\omega_{BA}^n = AB \cdot \omega_{AB}^2 = 4 \text{ m/sec}^2. \quad (c)$$

4) **Determination of ω_{Bn} .** Knowing the path of point B , we can determine its normal acceleration ω_{Bn} . For this, applying the theorem of projections (or the instantaneous centre of zero velocity P), we first determine the velocity v_B . We have $v_B \cos 45^\circ = v_A$, whence $v_B = v_A \sqrt{2}$. Therefore,

$$\omega_{Bn} = \frac{v_B^2}{BC} = \frac{2v_A^2}{r\sqrt{2}} = 8\sqrt{2} \text{ m/sec}^2. \quad (d)$$

Note: If a velocity diagram has been constructed for the mechanism, then

a) the value of ω_{AB} can be found from Eq. (58): $\omega_{AB} = \frac{ab}{AB}$. Then the computations in sections 2 and 3 can be omitted and ω_{BA}^n found directly from the equation,

$$\omega_{BA}^n = AB \cdot \omega_{AB}^2 = \frac{(ab)^2}{AB}.$$

b) the value of v_B for determining ω_{Bn} can also be obtained directly from the velocity diagram.

5) **Determination of w_B .** Note that, on the one hand, $w_B = w_{B\tau} + w_{Bn}$ and, on the other hand, w_B is given by Eq. (62). It follows, then, that

$$w_A + w_{BA}^n + w_{BA}^\tau = w_{Bn} + w_{B\tau}. \quad (e)$$

Let us express this equation graphically. From an arbitrary centre O_1 lay off to some scale vector $\overline{O_1a_1} = w_A$, from point a_1 lay off vector $\overline{a_1k} = w_{BA}^n$ ($w_{BA}^n \uparrow \uparrow BA$), and from point k draw kb_1 perpendicular to a_1k . This

line gives the direction of \vec{w}_{BA} , and somewhere on it lies the tip of the required vector \vec{w}_B .

Now from point O_1 lay off vector $\overline{O_1n} = \vec{w}_{Bn}$ ($\vec{w}_{Bn} \uparrow \uparrow \overline{BC}$) and draw perpendicular to it nb_1 , which gives the direction of $\vec{w}_{B\tau}$. The tip of vector \vec{w} must lie on this line as well. Consequently, point b_1 , where kb_1 and nb_1 intersect, gives us the tip of vector \vec{w}_B . Thus, $\vec{w}_B = \overline{O_1b_1}$. Scaling O_1b_1 , we find that $\omega_B \approx 13 \text{ m/sec}^2$.

At the same time it follows from the construction that $\overline{kb_1} = \vec{w}_{BA}$ and $\overline{nb_1} = \vec{w}_{B\tau}$.

By constructing the accelerations of other points of the mechanism in the same way (and from the same centre O), we obtain an *acceleration diagram*.

6) Determination of ϵ_{AB} . Measuring the length of kb_1 , we find from Eq. (61)

$$|\epsilon_{AB}| = \frac{|\vec{w}_{BA}|}{AB} = \frac{kb_1}{AB}.$$

Applying the scale, we find that $|\epsilon_{AB}| = 20 \text{ sec}^{-2}$. It can be seen in the diagram that vector $\vec{v}_{BA} = \vec{v}_B - \vec{v}_A$ is directed opposite to \vec{w}_{BA} ; consequently, the rotation of rod AB is retarded and $\epsilon_{AB} = -20 \text{ sec}^{-2}$.

B. Analytical determination of \vec{w}_B . After the computations performed in sections 1-4, construct, as in the graphical solution, vector polygons expressing equation (e).

Now draw coordinate axis O_1x perpendicular to the unknown vector \vec{w}_{BA} and project on it both sides of the vector equation (e). We obtain

$$\omega_{BA}^n = \omega_{Bn} \cos 45^\circ - |\omega_{B\tau}| \cos 45^\circ,$$

whence

$$|\omega_{B\tau}| = \omega_{Bn} - \omega_{BA}^n \sqrt{2} = 8 \sqrt{2} - 4 \sqrt{2} = 4 \sqrt{2},$$

and finally

$$\omega_B = \sqrt{\omega_{B\tau}^2 + \omega_{Bn}^2} = 4 \sqrt{10} = 12.65 \text{ m/sec}^2.$$

If it is necessary to compute ϵ_{AB} , we project both sides of equation (e) on axis O_1n , which is perpendicular to $\vec{w}_{B\tau}$, and obtain:

$$-\omega_A \cos 45^\circ + \omega_{BA}^n \cos 45^\circ + |\omega_{B\tau}| \cos 45^\circ = \omega_{Bn},$$

whence

$$|\omega_{BA}| = \omega_A - \omega_{BA}^n + \omega_{Bn} \sqrt{2} = 20 \text{ m/sec}^2.$$

Finally

$$|\epsilon_{AB}| = \frac{|\omega_{BA}|}{AB} = 20 \text{ sec}^{-2}.$$

When v_B and $\omega_{B\tau}$ are determined, either graphically or analytically, the angular velocity and angular acceleration of the rockshaft BC can be found from the equations

$$\omega_{BC} = \frac{v_B}{BC}, \quad |\epsilon_{BC}| = \frac{|\omega_{B\tau}|}{BC}.$$

* If the direction of \vec{w}_B were immediately known, the vector $\vec{w}_B = \overline{O_1b_1}$ could be obtained at once as the intersection of kb_1 and $O_1b_1 \parallel \vec{w}_B$.

Solving them, we obtain: $\omega_{BC} = 4 \text{ sec}^{-1}$, $\epsilon_{BC} = -8 \text{ sec}^{-2}$ (the minus shows that ω_B is directed opposite to ω_B).

85. Instantaneous Centre of Zero Acceleration. If a rigid body is in non-translatory motion, at every moment there is in its section S or in a plane rigidly connected with it a point Q whose acceleration is zero. This point is called the *instantaneous centre of zero acceleration*. If we know the acceleration ω_A of an arbitrary point A of the body and the values of ω and ϵ , we can locate the instantaneous centre of zero acceleration by the following method:

1) Compute angle μ (Fig. 196) by the formula $\tan \mu = \frac{|\epsilon|}{\omega^2}$.

2) From point A draw AE at an angle μ to vector ω_A , the line being turned from ω_A in the direction of the rotation of the body if the rotation is accelerated, and opposite to that direction if the rotation is retarded.

3) Along AE lay off a segment

$$AQ = \frac{\omega_A}{\sqrt{\epsilon^2 + \omega^4}}. \quad (63)$$

Point Q thus obtained is the instantaneous centre of zero acceleration. For, from Eqs. (59) and (60),

$$\omega_Q = \omega_A + \omega_{QA}.$$

where $\omega_{QA} = QA \sqrt{\epsilon^2 + \omega^4}$. Substituting the value of QA from Eq. (63), we find that $\omega_{QA} = \omega_A$. Besides, vector ω_{QA} must make an angle μ with QA , and consequently vector ω_{QA} is parallel to ω_A but opposite in sense. Therefore, $\omega_{QA} = -\omega_A$ and $\omega_Q = 0$.

If point Q is taken as the pole, then, as $\omega_Q = 0$, the acceleration of any point M of the body is, by Eqs. (59) and (60),

$$\omega_M = \omega_Q + \omega_{MQ} = \omega_{MQ} \text{ and } \omega_M = QM \sqrt{\epsilon^2 + \omega^4}. \quad (64)$$

Thus, the acceleration of any point of a body is equal to its acceleration of rotation about the instantaneous centre of zero acceleration Q . And from (64) we have

$$\frac{\omega_M}{QM} = \frac{\omega_A}{QA} = \dots \text{ etc.}, \quad (65)$$

i.e., the acceleration of any point of a body is proportional to its distance from the instantaneous centre of zero acceleration. A diagram of the distribution of accelerations is given in Fig. 197.

It should be borne in mind that the positions of the instantaneous centre of zero velocity P and the instantaneous centre of zero acceleration Q at any given time do not coincide. For example, if a wheel rolls along a straight rail (see Fig. 198), the velocity of its centre C being constant ($v_C = \text{const.}$), the instantaneous centre of zero velocity is at point P ($v_P = 0$), but, as was shown in Problem 75, $\omega_P \neq 0$, and P is not the instantaneous centre of zero acceleration. In this case it is obviously located at C , since it is in uniform rectilinear motion and $\omega_C = 0$. The instantaneous centres of zero velocity and zero acceleration coincide only when a body rotates about a fixed axis.

Fig. 196.

Fig. 197.

The concept of instantaneous centre of zero acceleration is convenient in solving certain problems.

Problem 78. A wheel rolls along a straight rail so that the velocity v_C of its centre C is constant. Determine the acceleration of a point M on the rim of the wheel (Fig. 198).

Solution. As $v_C = \text{const.}$, then, as shown above, point C is the instantaneous centre of zero acceleration. The instantaneous centre of zero velocity is at P . Consequently,

$$\omega = \frac{v_C}{PC} = \frac{v_C}{R} = \text{const.},$$

$$\varepsilon = \frac{d\omega}{dt} = 0, \quad \tan \mu = \frac{\varepsilon}{\omega^2} = 0, \quad \mu = 0$$

and from Eq. (64) we obtain

$$w_M = CM\omega^2 = \frac{v_C^2}{R}.$$

Fig. 198.

Thus, the acceleration of any point M on the rim (including P) is equal to v_C^2/R and is directed towards the centre of the wheel, since angle $\mu = 0$.

Note that for point M this is not the normal acceleration, for the velocity of M is perpendicular to PM (see Problem 69) and consequently the tangent M_τ to the path of point M is directed along MD , while the principal normal Mn is directed along MP . Therefore, $w_{Mn} = w_M \cos \alpha$ and $w_{M\tau} = w_M \sin \alpha$.

Problem 79. Crank OA rotates with a constant angular velocity ω_{OA} (Fig. 199). Determine the acceleration of the slide block B and the angular acceleration of the connecting rod AB at the instant when $\angle BOA = 90^\circ$, if $OA = r$ and $AB = l$.

Fig. 199.

Solution. At the given instant the velocity of all points of the connecting rod is v_A (see Problem 71, Fig. 186b), the instantaneous centre of zero velocity is at infinity, and $\omega_{AB} = 0$. Therefore,

$$\tan \mu = \frac{\varepsilon_{AB}}{\omega_{AB}^2} = \infty \quad \text{and} \quad \mu = 90^\circ \quad (\varepsilon_{AB} \neq 0,$$

as otherwise, according to Eq. (64), the accelerations of all the points of AB would be zero, but $\omega_A \neq 0$).

The acceleration of point A is $w_A = w_{An} = r\omega_{OA}^2$ and is directed along AO . The acceleration of point B , which is in rectilinear motion, is directed along OB . It will be noticed from Fig. 197 that the acceleration of any point M of the body makes an angle μ with QM . In the present case $\mu = 90^\circ$, consequently QA and QB are perpendicular to w_A and w_B . Erecting these perpendiculars, we locate point Q . Writing the proportion (65),

$$\frac{w_B}{QB} = \frac{w_A}{QA},$$

where $QB = r$ and $QA = \sqrt{l^2 - r^2}$, we obtain

$$w_B = \frac{r^2}{\sqrt{l^2 - r^2}} \omega_{OA}^2.$$

The acceleration ω_M of any other point M of the connecting rod is perpendicular to QM ($\mu = 90^\circ$); the magnitude of ω_M is found from Eq. (65).

The angular acceleration ϵ_{AB} of the connecting rod is found from the equation $\omega_A = QA \cdot \epsilon_{AB}$ obtained from Eq. (64) at $\omega_{AB} = 0$. Hence,

$$\epsilon_{AB} = \frac{r}{\sqrt{l^2 - r^2}} \omega_{OA}^2.$$

Chapter 13

MOTION OF A RIGID BODY HAVING ONE FIXED POINT AND MOTION OF A FREE RIGID BODY

86. Motion of a Rigid Body Having One Fixed Point. Let us investigate the motion of a body having a fixed point O . A top, whose point of contact with the plane on which it spins is fixed relative to it, or any body, with a ball-and-socket joint are illustrations of such motion.

The position of a body having a fixed point O can, evidently, be specified by the position of any other two points A and B not collinear with O (otherwise, if A and B were fixed, the body could have turned round axis AB , which is impossible when point O , not lying on AB , is fixed).

To get a full picture of this type of motion, let us demonstrate the following *theorem of Euler-d'Alembert*: Any displacement of a rigid body having a fixed point O can be effected by a simple rotation of the body about a certain line through that point.

Let the body occupy position I in space at time t_1 , and at time t_2 let it occupy position II , as shown in Fig. 200 by the dashed contour.

Let us choose points A and B of the body, by which we shall specify its position in space, such that point A is arbitrary and point B is that point in space at time t_1 to which point A comes at time t_2 .

When the body occupies configuration II , point A moves to position A_1 , which was previously occupied by B , while B moves to some new position B_1 . To prove the theorem, let us pass a plane through points A , A_1 , and B_1 and erect a perpendicular OD to it from O . Note that $OA = OA_1 = OB_1$ and $AB = A_1B_1$, as the

Fig. 200.

body is rigid. But this means that $AD = A_1D = B_1D$, as the projections of equally inclined equal lines on the same plane.

Consequently, $\triangle ADA_1 = \triangle A_1DB_1$, whence $\angle ADA_1 = \angle A_1DB_1 = \Delta\theta$. If, now, the body is turned through angle $\Delta\theta$ about axis OD , triangle ADA_1 will move in its plane until it coincides with triangle A_1DB_1 , with point A moving to A_1 and B to B_1 . Thus, the body has been transferred from position I to position II by the simple rotation about axis OD through angle $\Delta\theta$.

Fig. 201.

This theorem asserts that the body *can* be moved from position I to position II by the simple rotation about axis OD ; this, of course, does not necessarily mean that the motion of the body in the time interval $\Delta t = t_2 - t_1$ was actually that of simple rotation. Actually the body may have been moved from one position to the other in some other way. However, the smaller the time interval Δt , i.e., the closer position II to position I , the closer will the rotation through angle $\Delta\theta$ about axis OD resemble the actual motion of the body. When the interval Δt is indefinitely diminished, axis OD will approach a certain limiting position OP called the *instantaneous axis of rotation* of the body. By a rotation about this axis through an infinitesimal angle $d\theta$, the body is brought from one position to another, infinitesimally close position (Fig. 201). The angular velocity

$$\omega = \lim_{\Delta t \rightarrow 0} \frac{\Delta\theta}{\Delta t},$$

with which the rotation is made is the *instantaneous angular velocity* of the body at the given time t . This angular velocity can be depicted by a vector ω along axis OP (see § 74).

Unlike a fixed axis, the instantaneous axis of rotation continuously changes its direction in space and in the body. Thus, the motion of a rigid body about a fixed point can be regarded as a series of infinitesimal rotations with angular velocity ω round many instantaneous axes of rotation through the fixed point (Fig. 202). The successive positions of the instantaneous axis of rotation generate a conic surface, and the tip A of vector ω describes a curve on that surface.

The *angular acceleration* ϵ of the body, which in the present case characterises the time rate of change of the angular velocity

Fig. 202.

ω both in magnitude and direction, is

$$\epsilon = \frac{d\omega}{dt}.$$

By analogy with Eq. (13) (§ 64), we conclude that vector ϵ is parallel to the tangent to the path of the tip of vector ω at point A (see Fig. 202). Thus, in this case, unlike the case of rotation about a fixed axis, the direction of vector ϵ does not coincide with that of vector ω .

87. Velocity and Acceleration of Any Point of a Body. Since at any moment of time a body moving about a fixed point has an instantaneous axis of rotation OP , the magnitude of the velocity of any point M of the body (Fig. 203) at that moment will be specified (by analogy with § 76) by the equation

$$v = \omega h, \quad (66)$$

where ω is the angular velocity of the body and h is the distance of point M from the instantaneous axis of rotation. The velocity vector \mathbf{v} is normal to plane MOP through the instantaneous axis and point M in the direction of the rotation of the body.

Fig. 203.

Eq. (66) is not always convenient for determining v , as (unlike the case in § 76) the quantity h changes with time. For the same reason we cannot obtain from Eq. (66) an expression for the acceleration of point M , as was done in § 76, where $h = \text{const.}$

Let us therefore develop another formula which would enable us to obtain directly the velocity vector \mathbf{v} for point M .

Consider the vector product $\omega \times \mathbf{r}$, where \mathbf{r} is the radius vector from the fixed point O to the point M . The absolute value of the product is

$$|\omega \times \mathbf{r}| = \omega r \sin \alpha = \omega h.$$

Vectors $\omega \times \mathbf{r}$ and \mathbf{v} , it will be readily observed, have the same direction (the direction of a vector product was discussed in § 41) and dimension. Consequently,

$$\mathbf{v} = \omega \times \mathbf{r}, \quad (67)$$

i.e., the velocity vector for any point M of a body is equal to the vector product of the angular velocity of that body and the radius vector of the point.

From Eq. (67) we can obtain the acceleration of M :

$$\mathbf{w} = \frac{d\mathbf{v}}{dt} = \left(\frac{d\boldsymbol{\omega}}{dt} \times \mathbf{r} \right) + \left(\boldsymbol{\omega} \times \frac{d\mathbf{r}}{dt} \right).$$

But $\frac{d\boldsymbol{\omega}}{dt} = \boldsymbol{\varepsilon}$, and $\frac{d\mathbf{r}}{dt} = \mathbf{v}$, therefore

$$\mathbf{w} = (\boldsymbol{\varepsilon} \times \mathbf{r}) + (\boldsymbol{\omega} \times \mathbf{v}). \quad (68)$$

The acceleration $\mathbf{w}_1 = \boldsymbol{\varepsilon} \times \mathbf{r}$ is the rotational component, and $\mathbf{w}_2 = \boldsymbol{\omega} \times \mathbf{v}$ is the component of the acceleration of point M directed towards the axis of rotation. Vector \mathbf{w}_1 is normal to the plane through point M and vector $\boldsymbol{\varepsilon}$ (Fig. 204); in magnitude $w_1 = \varepsilon r \sin \beta = \varepsilon h_1$, where h_1 is the distance from point M to vector $\boldsymbol{\varepsilon}$. Vector \mathbf{w}_2 , which is perpendicular to both \mathbf{v} and $\boldsymbol{\omega}$, is directed along MC (see Figs 203 and 204), and in magnitude $w_2 = \omega v \sin 90^\circ = \omega^2 h$, as $v = \omega h$.

Problem 80. Determine the velocities of points B and C of the bevel wheel in Fig. 205 if the velocity v_A of the wheel centre A along its path is known. The wheel runs without slipping on the fixed conic surface K .

Fig. 204.

Fig. 205.

Solution. The wheel rotates about a fixed point O . As it runs without slipping, the points of the wheel on line OB must have the same velocity as the points of surface K , i.e., zero, and OB is the instantaneous axis of rotation of the wheel. Therefore $v_A = \omega h_1$, where ω is the angular velocity of the wheel in its motion about axis OB , and h_1 is the distance of A from that axis. Hence, $\omega = v_A/h_1$.

The velocity v_C of point C is ωh_2 , where h_2 is the distance of C from OB . As in this case $h_2 = 2h_1$, $v_C = 2v_A$. For point B , which is on the instantaneous axis of rotation, $v_B = 0$.

88. The Most General Motion of a Free Rigid Body. Let us now examine the most general motion of a rigid body free to move in any direction in space. In this case the position of the body relative to a frame of reference $Oxyz$ (Fig. 206) is, evidently, specified by the position of any three non-collinear points A, B, C of the body. Let the body occupy a position I at time t_1 , and at time t_2 let it be in position II . The displacement of the body in the time interval $\Delta t = t_2 - t_1$ can be performed in the following manner: first translate the body so that any arbitrary point A_1 (the pole) occupies a new position A_2 , the body as a whole occupying position I' . Now, to bring the body

into position II , it has to be rotated about the pole A_2 as round a fixed point. This, by the theorem in § 86, can be performed by a simple rotation of the body about line A_2D . Thus the body has been moved from position I to position II by first translating it and then rotating it about an axis AD through a pole A . However, for an arbitrary time interval Δt , this displacement does not give an actual picture of the body's motion. This can be obtained by dividing the duration of the motion into infinitesimal time intervals, for each of which the axis AD occupies a corresponding limiting position, i.e., that of the instantaneous axis of rotation,

Fig. 206.

We conclude, then, that the most general motion of a free rigid body is composed of a translation of the body, in which all its points move with a velocity \mathbf{v}_A in the same way as an arbitrary pole A , and a series of infinitesimal rotations with an angular velocity ω about the instantaneous axes of rotation through the pole A

(Fig. 207). This, for example, is the picture of motion in any non-translatory displacement of a body in air: a thrown stone, an aircraft engaged in stunt flying, a gun-shell, etc.

Plane motion of a free body (Chapter 12) can be treated as a special case in which the vector ω remains continually normal to the plane of motion. It should be noted

that both in the general case and in plane motion the rotational component of the motion (for instance, the value of ω) does not depend on the choice of the pole.

In the most general motion, as well as in plane motion (see § 79, Fig. 175), the velocity \mathbf{v}_M of any point M of a body is the resultant of the velocity \mathbf{v}_A of the pole A and the velocity \mathbf{v}_{MA} of point M in its rotation together with the body about A , i.e.,

$$\mathbf{v}_M = \mathbf{v}_A + \mathbf{v}_{MA}. \quad (69)$$

The validity of this result is proved as in § 79. And, from Eq. (67),

$$\mathbf{v}_{MA} = \omega \times \overline{AM}.$$

Fig. 207.

Similarly, we obtain for the acceleration of any point M (see § 84)

$$\mathbf{w}_M = \mathbf{w}_A + \mathbf{w}_{MA}. \quad (70)$$

The quantity \mathbf{w}_{MA} is given by Eq. (68), assuming $\mathbf{r} = \overline{AM}$ and $\mathbf{v} = \mathbf{v}_{MA} = \boldsymbol{\omega} \times \overline{AM}$.

Chapter 14

RESULTANT MOTION OF A PARTICLE

89. Relative, Transport, and Absolute Motion. So far we have considered the displacement of a particle or body with respect to one given frame of reference. But in solving problems of mechanics it is often more expedient (and sometimes necessary) to consider the motion of a particle (or body) simultaneously with respect to two frames of reference, one of which is assumed to be fixed and the other moving in some specified way with reference to the first. The motion performed in this case by the particle (or body) is called resultant, or combined motion.

For example, when a sphere rolls on the deck of a moving boat its motion with respect to the shore is the resultant of its rolling relative to the deck (the moving frame of reference) and

Fig. 208.

its motion together with the deck with respect to the shore (the fixed frame of reference). Thus, the resultant motion of the sphere can be resolved into two simpler, and easier analysed, motions. The method of resolving a motion into simpler motions by introducing a supplementary moving frame of reference is widely employed in kinematic calculations, thereby underlining the practical value of the theory of resultant motion considered in this and the following

chapters. Furthermore, the conclusions of this theory are used in dynamics to investigate the relative equilibrium and motion of bodies subjected to the action of forces.

Consider the resultant motion of a particle M moving with respect to a frame of reference $Oxyz$ which is in turn moving with relation to another frame of reference $O_1x_1y_1z_1$, which we assume to be fixed (Fig. 208). (Each of these frames of reference is, of course, associated with a definite body, not shown in the diagram.) We shall employ the following definitions:

1. The motion performed by the particle M with respect to the moving coordinate system is called *relative motion* (this is the

motion seen by an observer moving together with the moving axes $Oxyz$). The path AB described by the particle in relative motion is called the *relative path*. The velocity of the motion along this path AB is called the *relative velocity* (denoted by the symbol \mathbf{v}_{rel}). The quantity characterising the time rate of change of the relative velocity \mathbf{v}_{rel} of the particle M in its motion along AB (i.e., in its relative motion) is called the *relative acceleration* (denoted by the symbol \mathbf{w}_{rel}).

2. The motion performed by the moving frame of reference $Oxyz$, together with all the points of space fixed with respect to it, relative to the fixed system $O_1x_1y_1z_1$, is, for the particle M , the *motion of transport*.

The velocity of the point fixed in the moving axes $Oxyz$ with which the particle M coincides at a given instant is called the *transport velocity* of the particle M at that instant (denoted by \mathbf{v}_t), and the acceleration of that point is called the *transport acceleration* of the particle M (denoted by \mathbf{w}_t). In other words, if we imagine the relative motion of particle M to be taking place on the surface of (or inside) a rigid body in which the moving coordinates $Oxyz$ are fixed, then the transport velocity (or acceleration) of particle M at any given instant is the velocity (or acceleration) of the point of the body which coincides with M at that instant.

It is evident that the transport acceleration characterises the time rate of change of the transport velocity \mathbf{v}_t of the moving frame of reference.

3. The motion of the particle with respect to the fixed frame of reference $O_1x_1y_1z_1$ is called the *absolute*, or *resultant*, motion. The path CD described in this motion is called the *absolute path*, the velocity is the *absolute velocity* (denoted \mathbf{v}_a), and the acceleration the *absolute acceleration* (denoted \mathbf{w}_a).

In the example cited in the beginning of this article, the motion of the sphere with respect to the deck is relative motion, and the velocity of this motion is the relative velocity of the sphere; the motion of the ship with respect to the shore is, for the sphere, the motion of transport, and the velocity of the point of the deck with which the sphere coincides at the given time is, for the sphere, the transport velocity; finally, the motion of the sphere with respect to the shore is the absolute motion of the sphere, and the velocity of that motion is the absolute velocity of the sphere.

In order to solve the relevant problems of kinematics it is necessary to establish the relationships between the velocities and accelerations of the relative, transport and absolute motions.

90. **Composition of Velocities.** Consider a particle M performing a resultant motion. Let the relative displacement of the particle along its path AB in the time interval $\Delta t = t_1 - t$ be specified by the vector $\overline{MM'}$ (Fig. 209a). In the same time interval, the path AB itself, moving together with the moving axes, occupies a new position A_1B_1 , and the point of curve AB coinciding with the particle M at time t performs a transport displacement $\overline{MM''}$. As a result of these displacements particle M will occupy a position M_1 , its absolute displacement in the time interval Δt being $\overline{MM_1}$. From the vector triangle $MM''M_1$ we have:

$$\overline{MM_1} = \overline{MM''} + \overline{M''M_1}.$$

Dividing the equation through by Δt and passing to the limit, we obtain

$$\lim_{\Delta t \rightarrow 0} \frac{\overline{MM_1}}{\Delta t} = \lim_{\Delta t \rightarrow 0} \frac{\overline{MM''}}{\Delta t} + \lim_{\Delta t \rightarrow 0} \frac{\overline{M''M_1}}{\Delta t}. \quad (71)$$

But by definition

$$\lim_{\Delta t \rightarrow 0} \frac{\overline{MM_1}}{\Delta t} = v_a, \quad \lim_{\Delta t \rightarrow 0} \frac{\overline{MM''}}{\Delta t} = v_{tr}.$$

As to the last component, since, at $\Delta t \rightarrow 0$, curve A_1B_1 tends to coincide with curve AB , in the limit we have

$$\lim_{\Delta t \rightarrow 0} \frac{\overline{M''M_1}}{\Delta t} = \lim_{\Delta t \rightarrow 0} \frac{\overline{MM'}}{\Delta t} = v_{rel}.$$

The obtained velocities are tangent to the corresponding paths (Fig. 209b).

Substituting all these values into Eq. (71), we obtain

$$v_a = v_{rel} + v_{tr}. \quad (72)$$

Fig. 209.

Thus, in resultant motion the absolute velocity of a point is the geometrical sum of the relative velocity and the transport velocity. This is known as the theorem of the composition of velocities. The construction in Fig. 209b is called the *parallelogram of velocities*.

If the angle between the directions of velocities v_{rel} and v_{tr} is α , then in magnitude

$$v_a = \sqrt{v_{rel}^2 + v_{tr}^2 + 2v_{rel}v_{tr}\cos\alpha}. \quad (73)$$

Eq. (72) can be obtained by another course of reasoning. Let the position of a moving particle with respect to the fixed axes $O_1x_1y_1z_1$ be specified by a radius vector r_1 (see Fig. 209a) and let vectors $\overline{MM'}$, $\overline{MM''}$, and $\overline{MM_1}$ be very small displacements performed in the time interval dt along the tangents to the respective paths through point M . Then vector $\overline{MM_1}$ will denote the total increment dr_1 received by vector r_1 in the time interval dt . Similarly, vector $\overline{MM'}$ is the increment $(dr_1)_{rel}$ received by vector r_1 during the time interval dt as a result of only the relative displacement of the particle along curve AB , and $\overline{MM''}$ is the increment $(dr_1)_{tr}$ received by vector r_1 as a result of only the transport displacement of curve AB . We have

$$dr_1 = (dr_1)_{rel} + (dr_1)_{tr}, \quad (74)$$

i.e., the total increment of vector r_1 in the infinitesimal time interval dt is the geometrical sum of its increments in the relative and transport motions. Dividing Eq. (74) through by dt , we have

$$\frac{dr_1}{dt} = \frac{(dr_1)_{rel}}{dt} + \frac{(dr_1)_{tr}}{dt}, \quad (74')$$

or $v_a = v_{rel} + v_{tr}$, as, by virtue of the definition, the ratios in Eq. (74') are respectively equal to v_a , v_{rel} , and v_{tr} .

The following problems of particle kinematics are solved with the help of the parallelogram of velocities: a) knowing v_{rel} and v_{tr} , to determine v_a ; b) knowing v_a and the directions of v_{rel} and v_{tr} , to determine the magnitudes of the latter two velocities; c) knowing v_a and v_{tr} , to determine the relative velocity of a particle from the equation

$$v_{rel} = v_a + (-v_{tr}).$$

Problem 81. Point M moves in a straight line along OA (Fig. 210) with a velocity u , while OA itself turns in the plane Ox_1y_1 round O with an angular velocity ω . Find the velocity of point M relative to the axes Ox_1y_1 , expressed as a function of the distance $OM = r$.

Solution. Consider the motion of point M as a resultant motion consisting of its relative motion along OA and its motion together with OA . Then the velocity u along OA is the relative velocity of the point. The rotational motion of OA about O is, for the point M , the motion of transport, and the velocity of the point of OA with which M coincides at the given instant is the latter's transport velocity v_{tr} . As this point of OA moves along a circle of radius $OM = r$, $v_{tr} = r\omega$ and is perpendicular to OM . Constructing a parallelogram with vectors

Fig. 210.

u and v_{tr} as its sides, we obtain the absolute velocity v_a of M relative to the axes Ox_1y_1 . As u and v are mutually perpendicular, in magnitude

$$v_a = \sqrt{u^2 + v^2}.$$

Problem 82. The current of a river of width h has a constant velocity v . A man can row a boat in motionless water with a velocity u . Determine the direction he should take in order to cross the river in the least possible time and the point where he will reach the opposite bank.

Fig. 211.

Solution. Assume that the boat has started from point O (Fig. 211). Draw the coordinate axes Ox_1y_1 and show the boat in an arbitrary position M . Assume further that the rower steers his boat at a constant angle α to axis Oy_1 . Then the absolute velocity v_a of the boat is compounded of the relative velocity v_{rel} imparted to it by the rower ($v_{rel} = u$) and the transport velocity v_{tr} , which is the velocity of the stream ($v_{tr} = v$):

$$v_a = v_{rel} + v_{tr} = u + v.$$

The projections of the absolute velocity on the coordinate axes are (according to the theorem of the projection of a vector sum):

$$v_{ax_1} = u \sin \alpha + v; \quad v_{ay_1} = u \cos \alpha.$$

As both projections are constant, the displacements of the boat along the coordinate axes are

$$x_1 = (u \sin \alpha + v) t; \quad y_1 = (u \cos \alpha) t.$$

When the boat reaches the opposite bank, $y_1 = h$, whence the duration of the crossing is

$$t_1 = \frac{h}{u \cos \alpha}.$$

Obviously t_1 will have the least value when $\cos \alpha = 1$, i.e., when $\alpha = 0$. Consequently, in order to cross the river in the shortest time, the rower should steer his boat perpendicular to the bank. This time is:

$$t_{\min} = \frac{h}{u}.$$

Assuming $\alpha = 0$ and $t = t_{\min}$ in the expression for x_1 , we have

$$x_1 = \frac{v}{u} h.$$

Thus, the boat will reach the other bank at a point B at a distance x_1 downstream from Oy_1 , directly proportional to v and h and inversely proportional to u .

Problem 83. At a given instant, the arm OM of a recording mechanism makes an angle α with the horizontal and the pencil M has a velocity v directed perpendicular to OM (Fig. 212). The drum with the paper rotates about a vertical axis with an angular velocity ω . Determine the velocity u of the pencil on the paper if the radius of the drum is a .

Solution. The absolute velocity of the pencil is $\mathbf{v}_a = \mathbf{v}$. Velocity \mathbf{v} can be regarded as the geometrical sum of the velocity of the pencil relative to the paper (i.e., the required velocity \mathbf{u}) and the transport velocity \mathbf{v}_{tr} , which is equal to the velocity of the point of the paper with which the pencil coincides at the given moment; its magnitude is $v_{tr} = \omega a$.

From the theorem of the composition of velocities we have $\mathbf{v} = \mathbf{u} + \mathbf{v}_{tr}$, whence $\mathbf{u} = \mathbf{v} + (-\mathbf{v}_{tr})$. Constructing a parallelogram with vectors \mathbf{v} and $(-\mathbf{v}_{tr})$ as its sides, we obtain the required velocity \mathbf{u} . As the angle between \mathbf{v} and $(-\mathbf{v}_{tr})$ is 90° , in magnitude

$$u = \sqrt{v^2 + \omega^2 a^2 + 2v\omega a \sin \alpha}.$$

The angle between \mathbf{u} and the direction of \mathbf{v}_{tr} can now be determined by the law of sines.

Fig. 212.

Fig. 213.

Problem 84. End B of a horizontal rod AB is hinged to a block sliding along the slots of a rocker OC and turns the latter round axis O (Fig. 213). The distance from O to AB is h . Find the dependence of the angular velocity of the rocker on the velocity v of the rod and angle φ .

Solution. The absolute velocity of the slide block equals the velocity v of the rod. It can be regarded as compounded of the relative velocity v_{rel} of the block in its motion in the slots of the rocker and the transport velocity v_{tr} , which is the velocity of the point of the rocker with which the block coincides at the given time. The directions of these velocities are along OB and perpendicular to OB , respectively. We obtain v_{rel} and v_{tr} by resolving velocity v along them. From the parallelogram we find that in magnitude $v_{tr} = v \cos \varphi$.

But, on the other hand, the transport velocity $v_{tr} = \omega \cdot OB = \omega \frac{h}{\cos \varphi}$, where ω is the angular velocity of the rocker. Equating these two expressions of v_{tr} , we obtain the angular velocity:

$$\omega = \frac{v}{h} \cos^2 \varphi.$$

91. Composition of Accelerations. Coriolis Theorem. Let us first define more accurately the concepts of the relative acceleration and acceleration of transport of a particle. In resultant motion, the increase of the relative velocity \mathbf{v}_{rel} of a particle takes place in both the relative and the transport components of

its motion, i.e., analogous to Eq. (74) in § 90: $d\mathbf{v}_{rel} = (d\mathbf{v}_{rel})_{rel} + (d\mathbf{v}_{rel})_{tr}$. But by definition the relative acceleration of a particle is the quantity \mathbf{w}_{rel} which characterises the time rate of change of its relative velocity \mathbf{v}_{rel} *only in the relative motion*. Consequently,

$$\mathbf{w}_{rel} = \frac{(d\mathbf{v}_{rel})_{rel}}{dt}. \quad (75)$$

The change of vector \mathbf{v}_{rel} due to the motion of transport is not taken into account by \mathbf{w}_{rel} .

Similarly, the transport velocity \mathbf{v}_{tr} changes both in the relative and the transport components of the motion, whence $d\mathbf{v}_{tr} = (d\mathbf{v}_{tr})_{rel} + (d\mathbf{v}_{tr})_{tr}$. But by definition the transport acceleration of a particle is the quantity \mathbf{w}_{tr} which characterises the time rate of change of the transport velocity *only in the motion of transport* (\mathbf{w}_{tr} is the acceleration of a point fixed in a set of moving axes, i.e., not performing relative motion). Consequently,

$$\mathbf{w}_{tr} = \frac{(d\mathbf{v}_{tr})_{tr}}{dt}. \quad (76)$$

The change which vector \mathbf{v}_{tr} receives in the relative motion is not taken into account by \mathbf{w}_{tr} .

Thus, unlike the velocities, the quantities which we define in kinematics as the relative acceleration and the transport acceleration when compounded do not give the total (absolute) acceleration of the particle. The definitions, however, are convenient insofar as they are useful in calculating the values of \mathbf{w}_{rel} and \mathbf{w}_{tr} . For since in determining \mathbf{w}_{rel} we do not have to take into account the motion of the moving axes $Oxyz$, the former can be calculated by the usual methods of particle kinematics (see §§ 67 and 69). Furthermore, since in calculating \mathbf{w}_{tr} we do not have to take into account the relative displacement of the particle, it is calculated as the acceleration of some rigid body fixed in the axes $Oxyz$, i.e., by the methods of rigid body kinematics (see §§ 76, 84, etc.). Thus, with the definitions of \mathbf{w}_{rel} and \mathbf{w}_{tr} given by Eqs. (75) and (76), they can be calculated by applying the known formulas of kinematics.

The fact that each of the vectors \mathbf{v}_{rel} and \mathbf{v}_{tr} do change in both the relative and transport components of the motion is illustrated by the following particular case. Let a particle be moving with acceleration along a straight line Ox , which itself rotates about an origin O in a plane Ox_1y_1 (see Problem 81). Then, during the relative displacement of the particle from position M to M' (Fig. 214a), vector \mathbf{v}_{rel} will change into \mathbf{v}'_{rel} (which is not shown in the diagram), the increment in the time interval dt being $(d\mathbf{v}_{rel})_{rel}$, the ratio of which to dt gives the relative acceleration \mathbf{w}_{rel} of the particle. But simultaneously,

due to the rotation of Ox , vector \mathbf{v}_{rel} will be displaced to position \mathbf{v}_{rel}' , its increment in the motion of transport being $(d\mathbf{v}_{rel})_{tr}$, the ratio of which to dt gives a supplementary acceleration, not included in the term \mathbf{w}_{rel} .

Similarly, in the motion of transport (the rotation of Ox), particle M is displaced in the time interval dt to position M'' (Fig. 214b) and the vector \mathbf{v}_{tr} becomes \mathbf{v}_{tr}' , its increment being $(d\mathbf{v}_{tr})_{tr}$, the ratio of which to dt gives the transport acceleration \mathbf{w}_{tr} of the particle. But at the same time, during the relative displacement of the particle from position M to M' , the vector \mathbf{v}_{tr} receives an additional increment $(d\mathbf{v}_{tr})_{rel}$, since, in position M , $\mathbf{v}_{tr} = \omega \cdot OM$, and in position M' , $\mathbf{v}_{tr}' = \omega \cdot OM'$. The ratio of this increment to dt gives a supplementary acceleration not included in the term \mathbf{w}_{tr} .

Fig. 214.

Now let us prove the theorem of the composition of accelerations. The absolute acceleration of a particle is $\mathbf{w}_a = \frac{d\mathbf{v}_a}{dt}$. As in resultant motion $\mathbf{v}_a = \mathbf{v}_{rel} + \mathbf{v}_{tr}$, it follows that

$$\mathbf{w}_a = \frac{d\mathbf{v}_{rel}}{dt} + \frac{d\mathbf{v}_{tr}}{dt}.$$

The total increments $d\mathbf{v}_{rel}$ and $d\mathbf{v}_{tr}$ of the respective vectors in the right side of the equation consist, as shown above, of their respective increments in the relative and transport components of the motion. Separating these increments, we can write the last equation in the form

$$\mathbf{w}_a = \frac{(d\mathbf{v}_{rel})_{rel}}{dt} + \frac{(d\mathbf{v}_{rel})_{tr}}{dt} + \frac{(d\mathbf{v}_{tr})_{rel}}{dt} + \frac{(d\mathbf{v}_{tr})_{tr}}{dt},$$

or taking into account Eqs. (75) and (76),

$$\mathbf{w}_a = \mathbf{w}_{rel} + \mathbf{w}_{tr} + \frac{(d\mathbf{v}_{rel})_{tr}}{dt} + \frac{(d\mathbf{v}_{tr})_{rel}}{dt}. \quad (77)$$

1. The Case of Translatory Motion of Transport. The last two components in Eq. (77) take into account the change of the relative velocity \mathbf{v}_{rel} in the motion of transport and the

transport velocity \mathbf{v}_{tr} in the relative motion. Let us first determine the values of these components in the case when the motion of the moving set of axes $Oxyz$ —and of curve AB (see Fig. 208) together with them—is translatable. In this case the transport displacement of AB into configuration A_1B_1 is such that vector \mathbf{v}_{rel} remains parallel to itself, i.e., it receives no increment (Fig. 215a; the moving axes are not shown). Consequently, in the present case $(d\mathbf{v}_{rel})_{tr} = 0$.

Fig. 215.

Furthermore, since AB is in translatable motion, the transport velocity (the velocity of all the points belonging to AB) is the same in position M' as in position M (Fig. 215b). Therefore, in the present case vector \mathbf{v}_{tr} does not change during the transport displacement of the particle from M to M' , and $(d\mathbf{v}_{tr})_{rel} = 0$. Thus, from Eq. (77) we obtain

$$\mathbf{w}_a = \mathbf{w}_{rel} + \mathbf{w}_{tr}. \quad (78)$$

Thus, in translatable motion of transport the absolute acceleration of a particle is equal to the geometrical sum of its relative and transport accelerations.

2. The Case of Non-Translatable Motion of Transport. In this case the quantities $(d\mathbf{v}_{rel})_{tr}$ and $(d\mathbf{v}_{tr})_{rel}$ are not zero. Let us introduce the symbol

$$\mathbf{w}_{cor} = \frac{(d\mathbf{v}_{rel})_{tr}}{dt} + \frac{(d\mathbf{v}_{tr})_{rel}}{dt}. \quad (79)$$

The quantity \mathbf{w}_{cor} , which characterises the time rate of change of the vector of relative velocity \mathbf{v}_{rel} in the motion of transport and the time rate of change of the vector of the transport velocity \mathbf{v}_{tr} in the relative motion, is called the *supplementary, or Coriolis, acceleration* of the particle. Then, from Eq. (77), we obtain

$$\mathbf{w}_a = \mathbf{w}_{rel} + \mathbf{w}_{tr} + \mathbf{w}_{cor}. \quad (80)$$

Eq. (80) expresses the following theorem of Coriolis*:

In non-translatory motion of transport, the absolute acceleration of a particle is equal to the geometrical sum of three accelerations: the relative acceleration, which characterises the time rate of change of the relative velocity in the relative motion, the transport acceleration, which characterises the time rate of change of the transport velocity in the transport motion, and the Coriolis acceleration, which characterises the time rate of change of the relative velocity in the transport motion and of the transport velocity in the relative motion.

92. Calculation of Coriolis Acceleration. In the most general transport motion, the motion of a set of axes $Oxyz$ is the result of a translation together with some pole and a rotation about that pole (§ 88), the rotational component of the motion being independent of the choice of the pole. In order to calculate the Coriolis acceleration of a particle for the most general case, it is necessary to determine the components of the right side of equation (79).

a) **Determination of $(d\mathbf{v}_{rel})_{tr}$.** In the transport displacement of a set of axes $Oxyz$ together with a curve AB (Fig. 216a; axes $Oxyz$ are not shown), vector \mathbf{v}_{rel} , which is tangent to AB , in a time interval dt will suffer a translation to point M'' and a rotation about that point to a position \mathbf{v}''_{rel} . The resultant increment of vector \mathbf{v}_{rel} is $(d\mathbf{v}_{rel})_{tr}$, which can be calculated by the formula $(d\mathbf{v}_{rel})_{tr} = \mathbf{v}_b dt$, where \mathbf{v}_b is the velocity of the displacement of point b , i.e., of the tip of vector $\overline{M''b} = \mathbf{v}_{rel}$ in its rotation about M'' . But this rotation is performed with a transport angular velocity $\boldsymbol{\omega}_{tr}$, i.e., with the angular velocity of rotation of the moving set of axes (Fig. 216b). Hence, by Eq. (67), $\mathbf{v}_b = \boldsymbol{\omega}_{tr} \times \overline{M''b} = \boldsymbol{\omega}_{tr} \times \mathbf{v}_{rel}$, and $(d\mathbf{v}_{rel})_{tr} = \mathbf{v}_b dt = (\boldsymbol{\omega}_{tr} \times \mathbf{v}_{rel}) dt$, whence

$$\frac{(d\mathbf{v}_{rel})_{tr}}{dt} = \boldsymbol{\omega}_{tr} \times \mathbf{v}_{rel}. \quad (81)$$

Fig. 216a.

* Gustave Coriolis (1792-1843)—a French scientist famous for his works in theoretical and applied mechanics.

b) Determination of $(d\mathbf{v}_{tr})_{rel}$. The transport velocity \mathbf{v}_{tr} is equal to the velocity of that point of AB fixed in the moving set of axes $Oxyz$ which coincides with particle M at the given instant (Fig. 216b). Taking the origin O as the pole, this velocity will consist of the velocity \mathbf{v}_o of the origin and the velocity of rotation of the axes about their origin. Consequently, from Eqs. (67) and (69), $\mathbf{v}_{tr} = \mathbf{v}_o + \boldsymbol{\omega}_{tr} \times \mathbf{r}$, where $\mathbf{r} = \overline{OM}$ and $\boldsymbol{\omega}_{tr}$ is the angular velocity of rotation. The relative displacement of the particle in the time interval dt is $\overline{MM'} = \mathbf{v}_{rel} dt$, and its new position is M' , for which $\mathbf{v}'_{tr} = \mathbf{v}_o + \boldsymbol{\omega}_{tr} \times \mathbf{r}'$, where $\mathbf{r}' = \mathbf{r} + \overline{MM'}$. Consequently, the increment to vector \mathbf{v}_{tr} due to the relative displacement of the particle from position M to M' is

$$(d\mathbf{v}_{tr})_{rel} = \mathbf{v}'_{tr} - \mathbf{v}_{tr} = \boldsymbol{\omega}_{tr} \times (\mathbf{r}' - \mathbf{r}) = \boldsymbol{\omega}_{tr} \times \overline{MM'} = \boldsymbol{\omega}_{tr} \times \mathbf{v}_{rel} dt,$$

whence

$$\frac{(d\mathbf{v}_{tr})_{rel}}{dt} = \boldsymbol{\omega}_{tr} \times \mathbf{v}_{rel}. \quad (82)$$

Substituting the expressions (81) and (82) into Eq. (79), we obtain

$$\mathbf{w}_{cor} = 2(\boldsymbol{\omega}_{tr} \times \mathbf{v}_{rel}). \quad (83)$$

Thus, the Coriolis acceleration of a particle is equal to the double vector product of the angular velocity of the motion of transport and the relative velocity of the particle. If the angle between the vectors \mathbf{v}_{rel} and $\boldsymbol{\omega}_{tr}$ is α , then in magnitude

$$w_{cor} = 2 |\boldsymbol{\omega}_{tr} \mathbf{v}_{rel}| \sin \alpha. \quad (84)$$

The vector \mathbf{w}_{cor} is of the same sense as the vector $\boldsymbol{\omega}_{tr} \times \mathbf{v}_{rel}$ i.e., normal to the plane through vectors $\boldsymbol{\omega}_{tr}$ and \mathbf{v}_{rel} in the direction from which a counterclockwise rotation would be seen to carry vector $\boldsymbol{\omega}_{tr}$ into vector \mathbf{v}_{rel} through the smaller angle (Fig. 217a).

It can also be seen from Fig. 217a that the direction of vector \mathbf{w}_{cor} can be obtained by projecting vector \mathbf{v}_{rel} on plane P , which is normal to $\boldsymbol{\omega}_{tr}$, and turning the projection \mathbf{v}_{rel}^P through 90° in the direction of the rotation of transport.

Fig. 216b.

Fig. 217.

If a resultant motion is in a *plane* (the relative path is a plane curve moving in its plane), then angle $\alpha = 90^\circ$ (Fig. 217b) and in magnitude

$$\omega_{\text{cor}} = 2 |\omega_{\text{tr}} \cdot v_{\text{rel}}|. \quad (85)$$

It can be seen from Fig. 217b that in the case of plane motion the direction of ω_{cor} can be obtained by turning the vector of the relative velocity v_{rel} through 90° in the direction of the rotation of transport (i.e., clockwise or counterclockwise, depending on the sense of the rotation).

To illustrate the above, Fig. 218 shows the direction of the Coriolis acceleration of a bead M moving in a tube AB for the cases when the tube itself turns in the plane of the diagram (Fig. 218a) and when it describes a cone (Fig. 218b).

Fig. 218.

From Eq. (84) we see that the Coriolis acceleration is zero when:

1) $\omega_{\text{tr}} = 0$, i.e., if the motion of transport is translatory (Eq. (78)) or if the angular velocity of the rotation of transport becomes zero at a given instant.

2) $v_{\text{rel}} = 0$, i.e., if there is no relative motion or if the relative velocity becomes zero at a given instant.

3) Angle $\alpha = 0$ or $\alpha = 180^\circ$, i.e., if the relative motion is parallel to the axis of the rotation of transport or if vector v_{rel} is parallel to that axis at a given instant.

93. Solution of Problems. A. Translatory Motion of Transport. When the motion of transport is translatory, the nature of the problems and the methods of their solution are analogous to the problems on the composition of velocities (§ 90).

Problem 85. A wedge moving horizontally with an acceleration w_1 pushes up a rod moving in vertical slides (Fig. 219). Determine the acceleration of the rod if the angle of the wedge is α .

Solution. The absolute acceleration w_A of point A is directed vertically up. It can be regarded as consisting of a relative acceleration w_{rel} directed along the side of the wedge and a transport acceleration w_{tr} , which is equal to the acceleration of the wedge w_1 . As the motion of transport of the wedge is translatory, by drawing a parallelogram on the basis of Eq. (78), and taking into account that $w_{\text{tr}} = w_1$, we obtain

$$w_A = w_1 \tan \alpha,$$

which is the acceleration of the rod.

B. Rotational Motion of Transport. Let us investigate in general form the determination of \mathbf{w}_a when the motion of transport is a rotation about any fixed axis.

Let a particle M be moving along a relative path AMB on the surface of a body (say a sphere) rotating with retardation about an axis BA (Fig. 220). In order to find the absolute acceleration of the particle at a given time t_1 , we must know for that instant: 1) the position of the particle on the curve AB ;

Fig. 219.

2) the relative velocity v_{rel} of the particle; 3) the angular velocity ω and the angular acceleration ϵ of the body (i.e., ω and ϵ of the motion of transport). If these quantities are not given, they should be determined from the conditions of the problem.

The next step is to draw the moving particle in its position at time t_1 and show vectors v_{rel} and ω in the diagram. The further computations are then as follows.

1) Determination of w_{rel} . Mentally stop the rotation of the body and calculate the acceleration of the particle in its motion along AB according to the formulas of

particle kinematics. If AB is given, then (§ 69)

$$w_{rel}^{\tau} = \frac{dv_{rel}}{dt}; \quad w_{rel}^n = \frac{v_{rel}^2}{\rho_{rel}},$$

where ρ_{rel} is the radius of curvature of AB at point M . If the relative motion is described by the coordinate method, then v_{rel} and w_{rel} are calculated according to the formulas of § 67.

2) Determination of w_{tr} . Calculating the acceleration of that point of the body with which the particle M coincides at the given moment, we obtain the transport acceleration from the formulas of rigid-body kinematics (§ 76):

$$w_{tr}^{\tau} = h\epsilon, \quad w_{tr}^n = h\omega^2,$$

where $h = MD$ is the distance of M from the axis of rotation at time t_1 .

3) Determination of w_{cor} . The calculation is according to the procedure explained in § 92.

4) Determination of w_a . Draw all the computed vectors on the diagram (taking into account their directions). From Coriolis theorem we have

$$\mathbf{w}_a = \mathbf{w}_{rel}^{\tau} + \mathbf{w}_{rel}^n + \mathbf{w}_{tr}^{\tau} + \mathbf{w}_{tr}^n + \mathbf{w}_{cor}.$$

If it is difficult to obtain the sum of the vectors in the right side of the equation geometrically, draw an arbitrary set of rectangular axes $Mxyz$ (see Fig. 220) and compute the projections of all the component vectors on these axes. Then, from the theorem of the projection of a vector sum, we have

$$w_{ax} = \sum w_{ix}, \quad w_{ay} = \sum w_{iy}, \quad w_{az} = \sum w_{iz},$$

Fig. 220.

and finally

$$w_a = \sqrt{w_{ax}^2 + w_{ay}^2 + w_{az}^2}$$

Note: In computing w_a be careful *not* to assume

$$w_a = \sqrt{w_{rel}^2 + w_{tr}^2 + w_{cor}^2}$$

(a characteristic mistake), as in the general case vectors w_{rel} , w_{tr} , and w_{cor} are not mutually perpendicular.

Problem 86. The rocker OA in Fig. 221 turns with a constant angular velocity ω about axis O . A block B slides along the slots with a constant relative velocity u . Determine the dependence of the absolute acceleration of the block on its distance x from O .

Solution. Stopping the rocker at time t_1 , we find that the relative motion of the block along it is uniform and rectilinear; consequently $w_{rel} = 0$.

For the block, the motion of the rocker is that of transport; consequently, the transport acceleration w_{tr} of the block is equal to the acceleration of the point of the rocker, with which the block coincides at the given time. Since that point of the rocker is moving in a circle of radius $OB = x$ and $\omega = \text{const.}$, vector $w_{tr} = w_{tr}''$ and is directed along BO . In magnitude $w_{tr} = w_{tr}'' = \omega^2 x$.

As the motion is in a plane, the Coriolis acceleration $w_{cor} = 2\omega u$. By turning the vector of the relative velocity u about point B through a right angle in the direction of the rotation of transport (clockwise), we obtain the direction of w_{cor} .

From Coriolis theorem,

$$w_a = w_{rel} + w_{tr} + w_{cor}$$

In the present case $w_{rel} = 0$ and w_{cor} is perpendicular to w_{tr} . Consequently,

$$w_a = \sqrt{w_{tr}^2 + w_{cor}^2} = \omega \sqrt{\omega^2 x^2 + 4u^2}.$$

Problem 87. The eccentric in Fig. 222 is a circular disc of radius R rotating with a uniform angular velocity ω about axis O through the rim of the disc. Sliding from point A along the disc with a constant relative velocity u is a pin M . Determine the absolute acceleration of the pin at any time t . The motions are directed as shown in the diagram.

Solution. At time t the pin is at a distance $s = \widehat{AM} = ut$ from A . Consequently, at that instant angle $AOM = \alpha$ will be

$$\alpha = \frac{s}{2R} = \frac{u}{2R} t, \quad (a)$$

as angle α is equal to half the central angle ACM .

Fig. 221.

Stopping the motion of the disc at time t , we find that the relative motion of the pin is along a circle of radius R . As $v_{\text{rel}} = u = \text{const.}$,

$$\omega_{\text{rel}}^{\tau} = \frac{du}{dt} = 0; \quad \omega_{\text{rel}}^n = \frac{u^2}{R}. \quad (\text{b})$$

The vector $\mathbf{w}_{\text{rel}} = \mathbf{w}_{\text{rel}}^n$ is directed along the radius MC .

For the pin the motion of the disc is that of transport. Hence, the transport acceleration \mathbf{w}_{tr} of the pin is equal to the acceleration of the point of the disc with which it coincides at the given time. This point moves in a circle of radius $OM = 2R \cos \alpha$. For the disc, $\omega = \text{const.}$, hence $\varepsilon = 0$, and

$$\omega_{\text{tr}}^{\tau} = OM \cdot \varepsilon = 0; \quad \omega_{\text{tr}}^n = OM \cdot \omega^2 = 2R\omega^2 \cos \alpha. \quad (\text{c})$$

Vector $\mathbf{w}_{\text{tr}} = \mathbf{w}_{\text{tr}}^n$ is directed along MO .

As the motion is in one plane,

$$\omega_{\text{cor}} = 2\omega u. \quad (\text{d})$$

The direction of \mathbf{w}_{cor} is found by turning vector $\mathbf{v}_{\text{rel}} = \mathbf{u}$ round point M through 90° in the direction of the motion of transport (counterclockwise).

The absolute acceleration of the pin is

$$\mathbf{w}_a = \mathbf{w}_{\text{rel}} + \mathbf{w}_{\text{tr}} + \mathbf{w}_{\text{cor}}.$$

In this case vectors \mathbf{w}_{rel} and \mathbf{w}_{cor} are collinear and can be replaced by a collinear vector \mathbf{w}_1 of magnitude $w_1 = w_{\text{rel}} - w_{\text{cor}}$.

Adding vectors \mathbf{w}_1 and \mathbf{w}_{tr} according to the parallelogram law, we obtain finally

$$w_a = \sqrt{w_{\text{tr}}^2 + (w_{\text{rel}} - w_{\text{cor}})^2 + 2w_{\text{tr}}(w_{\text{rel}} - w_{\text{cor}})\cos \alpha},$$

where the values of α , w_{rel} , w_{tr} , and w_{cor} are given by equations (a), (b), (c), (d).

Problem 88. A body in the Northern Hemisphere is translated from North to South along a meridian with a velocity $v_{\text{rel}} = u$ m/sec (Fig. 223). Determine the magnitude and direction of the Coriolis acceleration of the body at latitude λ .

Solution. Neglecting the dimensions of the body, we treat it as a particle. The relative velocity of the body \mathbf{u} makes an angle λ with the earth's axis. Consequently,

$$w_{\text{cor}} = 2\omega u \sin \lambda,$$

where ω is the angular velocity of the earth's rotation.

Thus, the Coriolis acceleration is greatest at the Pole, where $\lambda = 90^\circ$. As the body approaches the equator, the value of w_{cor} decreases, till it reaches zero at the equator, where the vector $\mathbf{v}_{\text{rel}} = \mathbf{u}$ is parallel to the axis of rotation of the earth.

The direction of \mathbf{w}_{cor} is found by the rule of a vector product. As $\mathbf{w}_{\text{cor}} = 2(\boldsymbol{\omega} \times \mathbf{u})$, we find that vector \mathbf{w}_{cor} is perpendicular to the plane through vectors \mathbf{u} and $\boldsymbol{\omega}$, i.e., perpendicular to the meridian plane, and is directed

Fig. 222.

Fig. 223.

eastwards, from where the shortest turn from vector ω to vector u is seen counterclockwise.

The question of how the Coriolis acceleration affects the motion of bodies at the earth's surface is studied in the course of dynamics. However, from the formula obtained it can be seen that the value of ω_{cor} is usually small, as the angular velocity of rotation of the earth is small:

$$\omega \approx \frac{2\pi}{24 \cdot 3,600} \text{ sec}^{-1}.$$

It is apparent, therefore, that for motions with small velocities the Coriolis acceleration can, for all practical purposes, be neglected.

Problem 89. The hypotenuse of the right-angled triangle ABC in Fig. 224 is $AB = 2a = 20$ cm, and $\angle CBA = \alpha = 60^\circ$. The triangle rotates about axis Cz_1 according to the law $\varphi = 10t - 2t^2$. Particle M oscillates along AB about its middle O , its equation of motion being $\xi = a \cos\left(\frac{\pi}{3}t\right)$ (axis $O\xi$ is directed along OA). Determine the absolute acceleration of the particle M at time $t_1 = 2$ sec.

Solution. 1) Determine the position of M on its relative path AB at time t_1 . From the equation of the motion we have

$$\xi_1 = a \cos\left(\frac{2\pi}{3}\right) = -\frac{a}{2},$$

i.e., at time t_1 the particle M is at the middle of segment OB . Show this position in the diagram.

2) Determination of v_{rel} . As the relative motion is rectilinear,

$$v_{\text{rel}} = \frac{d\xi}{dt} = -\frac{\pi}{3} a \sin\left(\frac{\pi}{3}t\right).$$

At time $t_1 = 1$ sec,

$$v_{\text{rel}1} = -\frac{\pi}{6} a \sqrt{3}; \quad |v_{\text{rel}1}| = \frac{5}{3} \pi \sqrt{3} \text{ cm/sec.}$$

The minus indicates that at the given instant t_1 the vector v_{rel} is pointed from M to B .

3) Determination of ω and ϵ . Differentiating, we obtain

$$\omega = \frac{d\varphi}{dt} = 10 - 4t, \quad \omega_1 = 2 \text{ sec}^{-1},$$

where ω_1 is the value of ω at time $t_1 = 2$ sec;

$$\epsilon = \frac{d\omega}{dt} = -4 \text{ sec}^{-2}.$$

The signs indicate that at time t_1 the rotation is counterclockwise (observed from the tip of axis Cz_1) and is retarded.

4) Determination of w_{rel} . As the relative motion is rectilinear,

$$w_{\text{rel}} = \frac{dv_{\text{rel}}}{dt} = -\frac{\pi^2}{9} a \cos\left(\frac{\pi}{3}t\right).$$

Fig. 224.

At time $t_1 = 2$ sec,

$$w_{\text{rel},1} = \frac{\pi^2}{18} a = \frac{5}{9} \pi^2 \text{ cm/sec}^2.$$

5) **Determination of w_{tr} .** For the particle M the motion of the triangle is that of transport, and the transport acceleration of M is equal to the acceleration of the point of the triangle with which M coincides at the given time. This point of the triangle moves in a circle of radius $MD = h$, and at time $t_1 = 2$ sec,

$$h_1 \frac{a}{2} \sin \alpha = 5 \frac{\sqrt{3}}{2} \text{ cm.}$$

Thus, at the given instant,

$$w_{\text{tr}}^{\tau} = \bar{e}h = -10\sqrt{3} \text{ cm/sec}^2; \quad w_{\text{tr}}^n = \omega^2 h = 10\sqrt{3} \text{ cm/sec}^2.$$

Vector w_{tr}^{τ} is normal to plane ABC in the direction opposite to that of the rotation of the triangle. Vector w_{tr}^n is directed along MD towards the axis of rotation Cz_1 .

6) **Determination of w_{cor} .** The magnitude of w_{cor} at time $t_1 = 2$ sec is

$$w_{\text{cor}} = 2 |\omega v_{\text{rel}}| \sin \alpha = 10\pi \text{ cm/sec}^2,$$

as in this case the angle between $v_{\text{rel},1}$ and axis Cz_1 is α .

Projecting vector v_{rel} on a plane perpendicular to Cz_1 (the projection lies along MD) and turning the projection through a right angle in the direction of the rotation of transport, i.e., counterclockwise, we obtain the direction of w_{cor} (which in the present case coincides with the direction of w_{tr}^{τ}).

7) **Determination of w_a .** The absolute acceleration of the particle M at time t_1 is

$$w_a = w_{\text{rel}} + w_{\text{tr}}^{\tau} + w_{\text{tr}}^n + w_{\text{cor}}.$$

In order to determine the value of w_a , draw a set of axes $Oxyz$ (see Fig. 224) and calculate the projections of all the vectors on them. We obtain

$$w_{ax} = w_{\text{cor}} + |w_{\text{rel}}^{\tau}| = 10\pi + 10\sqrt{3} \approx 48.7 \text{ cm/sec}^2,$$

$$w_{ay} = w_{\text{rel}} \sin \alpha - w_{\text{tr}}^n = \frac{5\pi^2}{18} \sqrt{3} - 10\sqrt{3} \approx -12.6 \text{ cm/sec}^2,$$

$$w_{az} = -w_{\text{rel}} \cos \alpha = -\frac{5}{18} \pi^2 \approx -2.7 \text{ cm/sec}^2,$$

and finally

$$w_a = \sqrt{w_{ax}^2 + w_{ay}^2 + w_{az}^2} \approx 50.4 \text{ cm/sec}^2.$$

Vector w_a can be constructed according to its rectangular components along the coordinate axes $Oxyz$.

Chapter 15

RESULTANT MOTION OF A RIGID BODY

94. Composition of Translatory Motions. If a body moves with respect to a set of moving axes $Oxyz$ (see Fig. 208) which are in transport motion relative to a fixed system $Ox_1y_1z_1$, the resulting absolute motion of the body is called resultant, or combined, motion (see § 89).

The problem of kinematics in this case is to determine the relation between the characteristics of the relative, transport, and absolute motions. As we know, the main kinematic characteristics of the motion of a body are its translatory and angular velocities and accelerations. We shall confine ourselves to establishing only the relations between the translatory and angular velocities of the motions.

Consider first the case when the relative motion of a body is a translation with a velocity \mathbf{v}_1 and the motion of transport is also a translation with a velocity \mathbf{v}_2 . Then in the relative motion all the points of the body will have a velocity \mathbf{v}_1 , and in the motion of transport, \mathbf{v}_2 . From the theorem of the composition of velocities, in the absolute motion all the points of the body will have the same velocity $\mathbf{v} = \mathbf{v}_1 + \mathbf{v}_2$, i.e., the absolute motion will be that of translation.

Thus, the resultant motion of two translatory motions with velocities \mathbf{v}_1 and \mathbf{v}_2 is also a translation with a velocity $\mathbf{v} = \mathbf{v}_1 + \mathbf{v}_2$.

The composition of velocities in this case is reduced to a problem in particle kinematics (§ 90).

95. Composition of Rotations About Two Parallel Axes. Consider the case of a relative rotational motion of a body with an angular velocity ω_1 about a shaft aa'

mounted on a crank ba (Fig. 225), and a rotational motion of transport of the crank ba round axis bb' with an angular velocity ω_2 .

If axes aa' and bb' are parallel, the body will be in plane motion perpendicular to the axes. Let us investigate the cases of rotations of same and opposite sense.

Fig. 225.

1) Rotations of Same Sense. The figure S in Fig. 226 is a cross section of a body perpendicular to the axes of rotation. Let us denote the points of intersection of the axes of rotation with the section by the letters A and B. It will be readily noticed

that, as A lies on the axis Aa' , its velocity is due only to the rotation about axis Bb' , whence $v_A = \omega_2 \cdot AB$. Similarly, $v_B = \omega_1 \cdot AB$. Vectors \mathbf{v}_A and \mathbf{v}_B are, of course, parallel, both being perpendicular to AB , and of opposite sense. Therefore, point C (see § 81, Fig. 182) is the instantaneous centre of zero velocity ($v_C = 0$), and, consequently, axis Cc' , which is parallel to both Aa' and Bb' , is the *instantaneous axis of rotation* of the body.

The angular velocity ω of the absolute rotation of the body about axis Cc' and the position of the axis i.e., of point C , can be determined from Eq. (55) (§ 81):

$$\omega = \frac{v_B}{BC} = \frac{v_A}{AC}.$$

By virtue of the properties of proportions, we obtain:

$$\omega = \frac{v_A + v_B}{AC + BC} = \frac{v_A + v_B}{AB}.$$

Substituting $v_A = \omega_2 \cdot AB$ and $v_B = \omega_1 \cdot AB$ into the last two equations, we finally obtain

$$\omega = \omega_1 + \omega_2, \quad (86)$$

$$\frac{\omega_1}{BC} = \frac{\omega_2}{AC} = \frac{\omega}{AB}. \quad (87)$$

Thus, if a body participates simultaneously in two rotations of same sense about parallel axes, the resultant motion will be an instantaneous rotation with an angular velocity $\omega = \omega_1 + \omega_2$ about an instantaneous axis parallel to the two given axes; the position of this axis is determined by the ratio (87).

The instantaneous axis of rotation Cc' moves with time, describing a cylindrical surface.

2) Rotations of Opposite Sense. Again draw a section S of the body under consideration (Fig. 227) and let us assume that $\omega_1 > \omega_2$.

Then, reasoning in the same way as above, we find that the magnitudes of the velocities of points A and B are respectively: $v_A = \omega_2 \cdot AB$, $v_B = \omega_1 \cdot AB$, the two velocities being parallel and

Fig. 226.

Fig. 227.

of same sense. The instantaneous axis of rotation passes through point C (Fig. 227) and

$$\omega = \frac{v_B}{BC} = \frac{v_A}{AC} = \frac{v_B - v_A}{BC - AC},$$

or

$$\omega = \frac{v_B - v_A}{AB}.$$

Substituting the values of v_A and v_B in these equations, we obtain finally

$$\omega = \omega_1 - \omega_2, \quad (88)$$

$$\frac{\omega_1}{BC} = \frac{\omega_2}{AC} = \frac{\omega}{AB}. \quad (89)$$

Thus, in this case, too, the resultant motion is an instantaneous rotation with absolute angular velocity $\omega = \omega_1 - \omega_2$, about the axis Cc' , the position of which is specified by the ratio (89).

These results show that in rotations about parallel axes the vectors of the angular velocities are compounded like the vectors of parallel forces (§ 17).

3) Couple of Rotations. Consider the special case of rotations of opposite sense about parallel axes (Fig. 228) in which in magnitude $\omega_1 = \omega_2$. Such a combination of rotations is called a *rotation couple*, and vectors ω_1 and ω_2 make an *angular velocity couple*. In this case we have $v_A = v_B = \omega_1 \cdot AB$. Then (see § 81, Fig. 181) the instantaneous centre or zero velocity lies at infinity and all points of the body have the same velocity $v = \omega_1 \cdot AB$.

Thus, the resultant motion of the body will be a *translation* (or an *instantaneous translation*) with a velocity v equal in magnitude to $\omega_1 \cdot AB$ and normal to the plane through vectors ω_1 and ω_2 ; the direction of vector v is determined in the same way as the direction of the moment m of a force couple in statics (§ 44). Thus, a *rotation couple is equivalent to a translation* (or an *instantaneous translation*) with a

velocity v equal to the moment of the angular velocities of the couple.

An example of such motion is the translatory displacement of a bicycle pedal DE with respect to the bicycle frame (Fig. 229)

Fig. 228.

Fig. 229.

resulting from the relative rotation of the pedal about axle A mounted on the crank BA and the rotational motion of transport of the crank about axle B . The angular velocities ω_1 and ω_2 of these rotations are equal in magnitude, as at any instant the angle of rotation of the pedal relative to the crank φ_1 is equal to the angle of rotation of the crank φ_2 . The velocity of the pedal's translatory motion will be $v = \omega_2 \cdot AB$.

96. **Toothed Spur Gearing.** The results obtained in the preceding section can be used for the kinematic calculation of spur gearing transmissions. Let us consider the main types of such transmissions.

Fig. 230.

Fig. 231.

1) A *common* gear train is one in which all the gears, which are meshed successively, rotate on fixed axes. One of the gears (e.g., gear 1 in Figs 230 and 231) is the driving gear, or driver, and the others are the driven gears, or followers. In the case of external (Fig. 230a) or internal (Fig. 230b) gearing with two wheels we have $|\omega_1| r_1 = |\omega_2| r_2$, as the velocity of the point of engagement A is the same for both gears. Since the number of teeth z of the gears is proportional to their radii, and taking into account that the rotation of the gears is in the same direction in the case of internal engagement and in opposite directions in the case of external engagement, we have*

$$\left(\frac{\omega_1}{\omega_2}\right)_{ext} = -\frac{r_2}{r_1} = -\frac{z_2}{z_1}; \quad \left(\frac{\omega_1}{\omega_2}\right)_{int} = \frac{r_2}{r_1} = \frac{z_2}{z_1}.$$

For a train of three external gears (Fig. 231) we have

$$\frac{\omega_1}{\omega_2} = -\frac{r_2}{r_1}; \quad \frac{\omega_2}{\omega_3} = -\frac{r_3}{r_2},$$

whence

$$\frac{\omega_1}{\omega_3} = \frac{r_3}{r_1} = \frac{z_3}{z_1}.$$

Consequently, the ratio of the angular velocities of the end gears in a straight drive is inversely proportional to their radii (the number of teeth) and does not depend on the radii of intermediate gears (idlers).

* In all the formulas of this section, ω is the algebraic (numerical) value of the angular velocity, "plus" indicating counterclockwise rotation and "minus" indicating clockwise rotation.

From the results obtained it follows that in a straight drive consisting of n gears

$$\frac{\omega_1}{\omega_n} = (-1)^k \frac{r_n}{r_1} = (-1)^k \frac{z_n}{z_1}, \quad (90)$$

where k is the number of *external* engagements (in the case of Fig. 230a there is one external engagement; in Fig. 231 there are two external engagements; in Fig. 230b there are no external engagements).

The gear ratio of a toothed drive is the quantity i_{1n} which gives the ratio of the angular velocity of the driver to that of the follower:

$$i_{1n} = \frac{\omega_1}{\omega_n}. \quad (91)$$

For a straight drive the value of i_{1n} is given by the right side of Eq. (90).

2) An *epicyclic* train, or planetary transmission (see Fig. 232) is one in which gear 1 is fixed while the other successively engaged gears are connected by a link AB , called an arm, which rotates about the axis of the fixed gear.

3) A *differential* transmission is again of the type in Fig. 232, with the difference that gear 1 also rotates about its axis independently of the arm AB .

Epicyclic trains can be calculated by mentally giving the fixed plane Ax_1y_1 a rotation with an angular velocity ω_{AB} equal in magnitude and opposite in sense to the angular velocity of the arm AB .

Fig. 232.

Then, by the results of § 95, the arm will be fixed in this resultant motion and any gear of radius r_k will have an angular velocity $\tilde{\omega}_k = \omega_k - \omega_{AB}$, where ω_k is the absolute angular velocity of this gear relative to the axes Ax_1y_1 . The axes of all the gears will be fixed and the dependence between $\tilde{\omega}_k$ can be found either by equating the velocities of the points of engagement or directly from Eq. (90).

Epicyclic trains can also be calculated with the help of instantaneous centres of zero velocity (§ 81).

Problem 90. In the epicyclic train in Fig. 232, gear 1 of radius r_1 is fixed and arm AB rotates with an angular velocity ω_{AB} . Determine the angular velocity of gear 3 of radius r_3 .

Solution. Let us denote the absolute angular velocities of the gears with respect to the axes Ax_1y_1 as ω_1 ($\omega_1 = 0$), ω_2 and ω_3 . Rotating the whole plane Ax_1y_1 with an angular velocity $-\omega_{AB}$, we obtain:

$$\tilde{\omega}_1 = 0 - \omega_{AB}, \quad \tilde{\omega}_2 = \omega_2 - \omega_{AB}, \quad \tilde{\omega}_3 = \omega_3 - \omega_{AB}, \quad \tilde{\omega}_{AB} = 0.$$

The number of external engagements in the resulting common gear train is $k = 2$. Then, from Eq. (90),

$$\frac{\tilde{\omega}_1}{\tilde{\omega}_3} = \frac{r_3}{r_1} \text{ or } \frac{-\omega_{AB}}{\omega_3 - \omega_{AB}} = \frac{r_3}{r_1}.$$

From this we find the absolute angular velocity of gear 3:

$$\omega_3 = \left(1 - \frac{r_1}{r_3}\right) \omega_{AB}.$$

If $r_3 > r_1$, the direction of rotation of gear 3 is the same as that of the arm; if $r_3 < r_1$, it is opposite. If $r_1 = r_3$, we obtain $\omega_3 = 0$, and gear 3 is in translatory motion.

The relative angular velocity of gear 3 (with respect to the arm AB) is found from Eq. (86). As the absolute velocity $\omega_3 = \omega_3^{rel} + \omega_{AB}$ (the angular velocity ω_{AB} of the arm is the transport velocity for gear 3), then

$$\omega_3^{rel} = \omega_3 - \omega_{AB} = -\frac{r_3}{r_1} \omega_{AB}.$$

At $r_3 = r_1$, we obtain $\omega_3^{rel} = -\omega_{AB}$. The relative, ω_3^{rel} , and transport, ω_{AB} , angular velocities form a couple, which in another way leads us to the same conclusion that the resultant motion of gear 3 in this case is a translation with a velocity $v = \omega_{AB} \cdot AB$.

Alternative solution*. The velocity of point B of gear 3 is $v_B = (r_1 + 2r_2 + r_3)\omega_{AB}$. We shall determine the velocity of point K of the gear, which is the point of engagement of gears 2 and 3. The velocity of gear 2 is $v_C = (r_1 + r_2)\omega_{AB}$. The instantaneous centre of zero velocity of the gear is at point P_2 , where it coincides with gear 1. Consequently, $v_K = 2v_C = 2(r_1 + r_2)\omega_{AB}$.

Then, by Eq. (56) (§ 81),

$$\omega_3 = \frac{|v_B - v_K|}{BK} = \frac{r_3 - r_1}{r_3} \omega_{AB}.$$

The same result can be obtained by constructing the centre of zero velocity P_3 of gear 3.

Problem 91. The reduction gear in Fig. 233 consists of a) a fixed gear 1; b) two pairs of twin pinions 2 and 3 mounted on a link connected with the driving shaft AC (the engagement of pinions 2 and 3 with gear 1 is internal); c) a gear 4 mounted on the driven shaft B . The number of teeth in the

gears are: $z_1 = 120$, $z_2 = 40$, $z_3 = 30$, $z_4 = 50$. The driving shaft makes $n_A = 1,500$ rpm. Determine the rpm of the driven shaft B .

Solution. Let us denote the absolute angular velocities: of shaft AC together with the link as ω_A ; of gear 4 together with shaft B as ω_B ; of the pinions 2 and 3 as ω_{23} (these gears rotate as a single body). Gear 1 has an angular velocity $\omega_1 = 0$. Rotating plane x_1y_1 parallel to which the mechanism moves, with an angular velocity $-\omega_A$, we obtain that the link in this imaginary motion is fixed ($\tilde{\omega}_A = 0$) and the velocities of the gears are

$$\tilde{\omega}_1 = 0 - \omega_A, \quad \tilde{\omega}_{23} = \omega_{23} - \omega_A, \quad \tilde{\omega}_4 = \omega_B - \omega_A.$$

* An alternative solution is given to show the possibility of employing the methods of § 81. Problems 91 and 92 could also have been solved this way, but usually this solution is more involved (especially for Problem 92).

Fig. 233.

Writing now Eq. (90) for gears 1 and 2, and 3 and 4, we obtain

$$\frac{\tilde{\omega}_1}{\tilde{\omega}_{23}} = \frac{z_2}{z_1}; \quad \frac{\tilde{\omega}_{23}}{\tilde{\omega}_4} = -\frac{z_4}{z_3}.$$

Multiplying the two equations, we have

$$\frac{\tilde{\omega}_1}{\tilde{\omega}_4} = -\frac{z_2 z_4}{z_1 z_3} \text{ or } \frac{-\omega_A}{\omega_B - \omega_A} = -\frac{z_2 z_4}{z_1 z_3},$$

whence, taking into account that the number of rpm is proportional to ω , we find

$$n_B = \left(1 + \frac{z_1 z_3}{z_2 z_4}\right) n_A = 4,200 \text{ rpm.}$$

Problem 92. Solve the last problem, assuming that gear 1 rotates at $n_1 = 1,100$ rpm in the same direction as shaft AC (a differential reduction gear).

Solution. The sequence of the solution is the same as in Problem 91, with the sole difference that now $\omega_1 \neq 0$ and ω_1 and ω_A are of same sense. Consequently $\tilde{\omega}_1 = \omega_1 - \omega_A$.

As a result, the ratio

$$\frac{\tilde{\omega}_1}{\omega_4} = -\frac{z_2 z_4}{z_1 z_3}$$

obtained in Problem 91 gives

$$\frac{\omega_1 - \omega_A}{\omega_B - \omega_A} = -\frac{z_2 z_4}{z_1 z_3},$$

whence, passing to rpm, we find

$$n_B = n_A + \frac{z_1 z_3}{z_2 z_4} (n_A - n_1) = 2,200 \text{ rpm.}$$

If gear 1 rotates in the opposite direction of the shaft AC, the sign of n_1 in the result obtained should be changed.

97. Composition of Rotations About Two Intersecting Axes. This type of motion can be visualised if in Fig. 225 axis aa' is assumed not parallel to, but coplanar with, axis bb' .

If the absolute motion of a body is the result of a relative rotation and a rotation of transport with angular velocities ω_1 and ω_2 about axes Oa and Ob intersecting at O (Fig. 234), then, evidently, the velocity of point O , as lying simultaneously on both axes, is zero.

Consequently, the resultant motion of the body is a motion about the fixed point O , which for every infinitesimal time interval represents an infinitesimal turn with an angular velocity ω about an instantaneous axis through point O (§ 86).

Fig. 234.

To determine vector ω , calculate the velocity of any point M of the body the radius vector of which is $\overline{OM} = \mathbf{r}$. In the relative motion about axis Oa , point M , by Eq. (67), has a velocity $\mathbf{v}_{rel} = \omega_1 \times \mathbf{r}$; in the motion of transport about axis Ob the velocity of the point is $\mathbf{v}_{tr} = \omega_2 \times \mathbf{r}_2$. Hence, the absolute velocity of M is

$$\mathbf{v}_a = \mathbf{v}_{rel} + \mathbf{v}_{tr} = (\omega_1 + \omega_2) \times \mathbf{r}.$$

On the other hand, since the resultant motion of the body is an instantaneous rotation with an angular velocity ω we must have

$$\mathbf{v}_a = \omega \times \mathbf{r}.$$

Similar results can be obtained for every point of the body (i.e., for any value of \mathbf{r}). We conclude, therefore, that

$$\omega = \omega_1 + \omega_2. \quad (92)$$

Thus, the resultant of rotational motions about two axes intersecting at any point O is an instantaneous rotation about an axis Oc through O the angular velocity ω of which is the geometrical sum of the relative angular velocity and the transport angular velocity. The instantaneous axis of rotation Oc is collinear with vector ω , i.e., it is directed along the diagonal of a parallelogram with vectors ω_1 and ω_2 as its sides.

Axis Oc changes its position with time, describing a conic surface with its apex at O .

Fig. 235.

Problem 93. Determine the absolute angular velocity of the roller in Fig. 235 (see Problem 80, § 87), if its radius $AC = R$, $OA = l$, and the velocity of point A is v_A .

Solution. The absolute motion of the roller is the result of its relative rotation about axis OA with an angular velocity ω_1 , and the transport rotation of crank OA about axis OB with an angular velocity ω_2 , where

$$\omega_2 = \frac{v_A}{l}.$$

The instantaneous axis of rotation, and consequently the vector of the absolute angular velocity ω , are directed along OC , as the velocity of point C is zero (see Problem 80). Constructing a parallelogram, we find that $\omega = \frac{\omega_2}{\sin \alpha}$.

As $\sin \alpha = \frac{R}{\sqrt{l^2 + R^2}}$, we obtain finally

$$\omega = \frac{v_A}{R} \sqrt{1 + \frac{R^2}{l^2}}.$$

The same result can be obtained (taking into account that OC is the instantaneous axis of rotation) from the equation $v_A = \omega h$, where $h = l \sin \alpha$.

The motion of the roller represents a succession of infinitesimal turns with an angular velocity ω round axis OC , which latter continuously changes its position, describing a circular cone with its apex at O .

98. Composition of a Translation and a Rotation. Screw Motion. Let us examine the resultant motion of a rigid body having a translation and a rotation. Three cases are possible.

1) The velocity of the translation is perpendicular to the axis of rotation ($\mathbf{v} \perp \omega$). Let the resultant motion of the body consist of a rotation about an axis Aa with an angular velocity ω and a translation with a velocity \mathbf{v} perpendicular to ω (Fig. 236). It is evident that with respect to plane P , which is perpendicular to Aa , this is plane motion, which is discussed in detail in Chapter 12. If point A is taken as the pole, the motion, like any plane motion, will actually consist of a translation with a velocity $\mathbf{v}_A = \mathbf{v}$, i.e., the velocity of the pole, and a rotation round the axis Aa through the pole.

Fig. 236.

Vector \mathbf{v} can be replaced by a couple of angular velocities ω' , ω'' (§ 95), where $\omega' = \omega$, and $\omega'' = -\omega$. The distance AP can be found from the equation $v = \omega' \cdot AP$, whence (taking into account that $\omega' = \omega$)

$$AP = \frac{v}{\omega}. \quad (93)$$

The resultant of vectors ω and ω'' is zero, and we find that the motion of the body can be treated as an instantaneous rotation about axis Pp with an angular velocity $\omega' = \omega$. This result was obtained earlier in another way (§ 81). Comparing Eqs. (53) and (93), it will be readily noticed that point P is the instantaneous centre of zero velocity ($v_P = 0$) for section (S) of the body. Thus, we see once again that the rotation of the body about Aa and Pp is with the same angular velocity ω , i.e., the rotational component of a motion does not depend on the choice of the pole (§ 77).

2) **Screw Motion** ($\mathbf{v} \parallel \omega$). If the resultant motion of a body consists of a rotation about an axis Aa with an angular velocity ω and a translation with a velocity \mathbf{v} , directed parallel to Aa (Fig. 237), it is called *screw motion*. Axis Aa is called the

axis of the screw. When vectors \mathbf{v} and $\boldsymbol{\omega}$ are in the same direction, then, according to the rule for the notation of $\boldsymbol{\omega}$, the screw is right-handed; if they are of opposite sense, the screw is left-handed.

The size of the translatory displacement of any point of the body lying on the axis of the screw during one complete turn is called the *pitch* h of the screw. If v and ω are constant, the pitch of the screw is said to be *constant*. Denoting the time of one complete turn as T , we obtain in this case $vT = h$, and $\omega T = 2\pi$, whence

$$h = 2\pi \frac{v}{\omega}.$$

Fig. 237.

Any point M of a screw with a constant pitch describes a screw line. The velocity of such a point M lying at a distance r from the axis of the screw is compounded of the translatory velocity \mathbf{v} and the rotational velocity ωr perpendicular to it. Consequently,

$$v_M = \sqrt{v^2 + \omega^2 r^2}.$$

Velocity \mathbf{v}_M is tangent to the screw line. If the cylindrical surface along which point M moves is cut along its generator and spread out, the screw lines will, evidently, turn into straight lines inclined at an angle α to the base of the cylinder such that $\tan \alpha = h/2\pi r$.

3) The velocity of translation makes an arbitrary angle with the axis of rotation. In this case the resultant motion of the body (Fig. 238a) is the same as discussed in § 88 (the most general motion of a free rigid body).

Let us resolve vector \mathbf{v} (Fig. 238b) into its components: 1) \mathbf{v}' collinear with

$\boldsymbol{\omega}$ ($v' = v \cos \alpha$), and 2) \mathbf{v}'' perpendicular to $\boldsymbol{\omega}$ ($v'' = v \sin \alpha$). Velocity \mathbf{v}'' can be replaced by an angular velocity couple such that $\boldsymbol{\omega}' = \boldsymbol{\omega}$ and $\boldsymbol{\omega}'' = -\boldsymbol{\omega}$ (as in Fig. 236), and vectors $\boldsymbol{\omega}$ and $\boldsymbol{\omega}''$ can be discarded. The distance AC is found from formula (93):

$$AC = \frac{v''}{\omega} = \frac{v \sin \alpha}{\omega}.$$

Fig. 238.

The body is thus left with a rotation with an angular velocity ω' and a translation with a velocity \mathbf{v}' . Thus, the distribution of the velocities of all the points of the body at any given instant is the same as in a screw motion about axis Cc with an angular velocity $\omega' = \omega$ and a translatory velocity $v' = v \cos \alpha$. The position of Cc changes with the motion of the body, which is why it is called the *instantaneous screw axis*.

As a result of these operations (Fig. 238*b*) we have passed from pole A to pole C , which demonstrates that even in the most general motion of a body the angular velocity does not depend on the choice of the pole ($\omega' = \omega$), and only the translatory velocity is affected ($\mathbf{v}' \neq \mathbf{v}$).

PART THREE

PARTICLE DYNAMICS

Chapter 16

INTRODUCTION TO DYNAMICS. LAWS OF DYNAMICS

99. Basic Concepts and Definitions. *Dynamics is that section of mechanics which treats of the laws of motion of material bodies subjected to the action of forces.*

The motion of bodies from a purely geometrical point of view was discussed in kinematics. Unlike kinematics, in dynamics the motion of bodies is investigated in connection with the acting forces and the inertia of the material bodies themselves.

The concept of force as a quantity characterising the measure of mechanical interaction of material bodies was introduced in the course of statics. But in statics we treated all forces as constant, without considering the possibility of their changing with time. In real systems, though, alongside of constant forces (gravity can generally be regarded as an example of a constant force) a body is often subjected to the action of variable forces whose magnitudes and directions change when the body moves. Variable forces may be both applied (active) forces and the reactions of constraints.

Experience shows that variable forces may depend in some specific ways on *time*, on the *position* of a body, or on its *velocity* (examples of dependence on *time* are furnished by the tractive force of an electric locomotive whose rheostat is gradually switched on or off, or the force causing the vibration of a foundation of a motor with a poorly centred shaft; the Newtonian force of gravitation or the elastic force of a spring depend on the *position* of a body; the resistance experienced by a body moving through air or water depends on the *velocity*). In dynamics we shall deal with such forces alongside of constant forces. The laws for the composition and resolution of variable forces are the same as for constant forces.

The concept of inertia of bodies arises when we compare the results of the action of an identical force on different material bodies. Experience shows that if the same force is applied to two different bodies initially at rest and free from any other

actions, in the most general case the bodies will travel different distances and acquire different velocities in the same interval of time.

Inertia is the property of material bodies to resist a change in their velocity under the action of applied forces. If, for example, the velocity of one body changes slower than that of another body subjected to the same force, the former is said to have greater inertia, and vice versa. The inertia of any body depends on the amount of matter it contains.

The quantitative measure of the inertia of body, which depends on the quantity of matter in the body, is called the mass of that body. In mechanics mass m is treated as a scalar quantity which is positive and constant for every body. The measurement of mass will be discussed in the following article.

In the most general case the motion of a body depends not only on its aggregate mass and the applied forces; the nature of motion may also depend on the dimensions of the body and the mutual position of its particles (i.e., on the distribution of its mass).

In the initial course of dynamics, in order to neglect the influence of the dimensions and the distribution of the mass of a body, the concept of a material point, or particle, is introduced.

A particle is a material body (a body possessing mass) the size of which can be neglected in investigating its motion.

Actually any body can be treated as a particle when the distances travelled by its points are very great as compared with the size of the body itself*. Furthermore, as will be shown in the dynamics of systems, a body in *translatory* motion can always be considered as a particle of mass equal to the mass of the whole body.

Finally, the parts into which we shall mentally divide bodies in analysing any of their dynamical characteristics can also be treated as material points.

Obviously, the investigation of the motion of a single particle should precede the investigation of systems of particles, and in particular of rigid bodies. Accordingly, the course of dynamics is conventionally subdivided into particle dynamics and the dynamics of systems of particles.

100. The Laws of Dynamics. The study of dynamics is based on a number of laws generalising the results of a wide range of

* For example, in studying the motion of a planet about the sun the planet can be treated as a particle.

experiments and observations of the motions of bodies—laws which have been verified in the long course of human history. These laws were first systematised and formulated by Isaac Newton in his classical work “Mathematical Principles of Natural Philosophy” published in 1687.

The First Law (the Inertia Law), discovered by Galileo in 1638, states: *A particle free from any external influences continues in its state of rest, or of uniform rectilinear motion, except in so far as it is compelled to change that state by impressed forces.* The motion of a body not subjected to any force is called motion under no forces, or *inertial* motion.

The inertia law states one of the basic properties of matter: that of being always in motion. It establishes the equivalence, for material bodies, of the states of rest and of motion under no forces. It follows, then, that if $\mathbf{F} = 0$, a particle is at rest or moves with a velocity of constant magnitude and direction ($\mathbf{v} = \text{const.}$); the acceleration of the particle is, evidently, zero ($\mathbf{w} = 0$). No external action is required to sustain inertial motion; such action is necessary only to change the motion. At the same time it can be asserted that if the motion of a particle is not inertial, there must be some force acting on it.

A frame of reference for which the inertia law is valid is called an *inertial system* (or, conventionally, a fixed system). Experience shows that, for our solar system, an inertial frame of reference has its origin in the centre of the sun and its axes pointed towards the so-called “fixed” stars. In solving most engineering problems a sufficient degree of accuracy is obtained by assuming any frame of reference connected with the earth to be an inertial system. The validity of this assumption will be proved in Chapter 20.

The Second Law (the Fundamental Law of Dynamics) establishes the mode in which the velocity of a particle changes under the action of a force. It states: *the product of the mass of a particle and the acceleration imparted to it by a force is proportional to the acting force; the acceleration takes place in the direction of the force.*

Mathematically this law is expressed by the vector equation.

$$m\mathbf{w} = \mathbf{F}. \quad (1)$$

The dependence between the magnitudes of the acceleration and the force is

$$mw = F. \quad (2)$$

The second law of dynamics, like the first, is valid only for an inertial system. It can be immediately seen from the law

that the measure of the inertia of a particle is its mass, since two different particles subjected to the action of the same force receive the same acceleration only if their masses are equal; if their masses are different, the particle with the larger mass (i.e., the more inert one) will receive a smaller acceleration, and vice versa.

A set of forces acting on a particle can, as we know, be replaced by a single resultant R equal to the geometrical sum of those forces. In this case the equation expressing the fundamental law of dynamics acquires the form

$$m\omega = R \quad \text{or} \quad m\omega = \sum F_k. \quad (3)$$

Measure of mass. Eq. (2) makes it possible to determine the mass of a body if its acceleration in translatory motion and the acting force are known. It has been established experimentally that under the action of the force of gravitation P all bodies falling to the earth (from a small height and in vacuo) possess the same acceleration g ; this is known as *the acceleration of gravity* or *of free fall**. Applying Eq. (2) to this motion, we obtain $mg = P$, whence

$$m = \frac{P}{g}. \quad (4)$$

Thus, *the mass of a body is equal to its weight divided by the acceleration of gravity g .*

The Third Law (the Law of Action and Reaction) establishes the character of mechanical interaction between material bodies. For two particles it states: *Two particles exert on each other forces equal in magnitude and acting in opposite directions along the straight line connecting the two particles.*

It should be noted that the forces of interaction between free particles (or bodies) do not form a balanced system, as they act on different objects. For example, if a piece of iron and a magnet are placed near each other on a smooth surface, they will move towards each other under the influence of their mutual attraction and not remain at rest. Since the magnitude of the force acting on each body is the same, it follows from the second law of dynamics that the accelerations of the two bodies will be inversely proportional to their masses.

The third law of dynamics, which establishes the character of interaction of material particles, plays an important part in the dynamics of systems.

* The law of free fall of bodies was discovered by Galileo. The value of g varies for different localities, depending on geographic latitude and elevation above sea level. At sea level on the latitude of Moscow $g = 9.8157 \text{ m/sec}^2$.

101. Systems of Units. The units of length and time were introduced in the course of kinematics. In order to measure dynamical quantities, it is necessary to select unit measures for mass m or force F . These units cannot both be arbitrary, insofar as they are related by Eq. (2). Thus, in dynamics we can use two systems of units based on different principles.

First Type of Unit Systems. The primary units in these systems are: 1) unit of length (e.g., centimetre or metre), 2) unit of time (e.g., second); 3) unit of mass (e.g., gram, kilogram, or ton of mass).

In these systems force is a derived unit. In the so-called physical system of units CGS (centimetre, gram, second), for instance, the unit of force is the dyne ($1 \text{ dyne} = 1 \text{ g cm/sec}^2$).

Second Type of Unit Systems. The fundamental units in these systems are: 1) unit of length (e.g., metre); 2) unit of time (e.g., second); 3) unit of force (e.g., kilogram or ton of force). In these systems mass is a derived unit (e.g., $1 \text{ kg sec}^2/\text{m}$).

The difference between the two types of systems is that in the one the mass unit is taken as a primary dynamical unit, while in the other force is a primary unit.

In engineering the so-called technical system of units, in which the fundamental units are metre, kilogram of force, and second, is most widely used. We, too, shall normally employ this system.

102. The Problems of Dynamics for a Free and a Constrained Particle. The problems of dynamics for a free particle are: 1) knowing the equation of motion of a particle, to determine the force acting on it (*the first problem of dynamics*); 2) knowing the forces acting on a particle, to determine its equation of motion (*the second, or principal, problem of dynamics*).

Both problems are solved with the help of Eq. (1) or (3), which express the fundamental law of dynamics, since they give the relation between acceleration w , i.e., the quantity characterising the motion of a particle, and the forces acting on it.

In engineering it is often necessary to investigate *constrained* motions of a particle, i.e., cases when constraints attached to a particle compel it to move along a given fixed surface or curve.

In such cases we shall use, as in statics, the axiom of constraints which states that *any constrained particle can be treated as a free body detached from its constraints provided the latter is represented by their reactions N* . Then the fundamental law of dy-

namics for the constrained motion of a particle takes the form

$$m\ddot{x} = \sum F_k^a + N, \quad (5)$$

where F_k^a denotes the applied forces acting on the particle.

For constrained motion, the first problem of dynamics will usually be: to determine the reactions of the constraints acting on a particle if the motion and applied forces are known. The second (principal) problem of dynamics for such motion will pose two questions: knowing the applied forces, to determine: a) the equation of motion of the particle and b) the reaction of its constraints.

103. Solution of the First Problem of Dynamics (Determination of the Forces if the Motion Is Known). If the acceleration of a moving particle is given, the applied force or the reaction of the constraint can be immediately found from Eq. (1) or (5). To calculate the reaction it is also necessary to know the applied forces. When the acceleration is not specified but the equation of motion is known, it is necessary first to calculate the acceleration from the formulas of kinematics (see §§ 59, 67, 69) and then to find the force (or reaction).

Fig. 239.

Fig. 240.

Problem 94. A balloon of weight P descends with an acceleration w . What weight (ballast) Q must be thrown overboard in order to give the balloon an equal upward acceleration?

Solution. The forces acting on the falling balloon are its weight P and the buoyancy force F (Fig. 239a). Hence, from Eq. (3)

$$\frac{P}{g} w = P - F.$$

After the ballast has been thrown out (Fig. 239b), the weight of the balloon becomes $P - Q$, the buoyancy force remaining the same. Hence, taking into account that now the balloon is rising, we have

$$\frac{P - Q}{g} w = F - (P - Q).$$

Eliminating the unknown force F from the equations, we obtain

$$Q = \frac{2P}{1 + \frac{g}{w}}.$$

Problem 95. A lift of weight P (Fig. 240) starts ascending with an acceleration ω . Determine the tension in the cable.

Solution. Considering the lift as a free body, replace the action of the constraint (the cable) by its reaction T . From Eq. (5) we obtain

$$\frac{P}{g} \omega = T - P,$$

whence

$$T = P \left(1 + \frac{\omega}{g} \right).$$

If the lift starts descending with the same acceleration, the tension in the cable will be

$$T_1 = P \left(1 - \frac{\omega}{g} \right).$$

Problem 96. The radius of curvature of a bridge at point A is R (Fig. 241). Determine the pressure exerted on the bridge at A by a motor car of weight P moving with a velocity v .

Fig. 241.

Solution. The normal acceleration of the car at point A is $\omega_n = \frac{v^2}{R}$. Acting on it are the force of gravity P and the reaction of the constraint N . Then, from Eq. (5),

$$\frac{P}{g} \frac{v^2}{R} = P - N,$$

whence

$$N = P \left(1 - \frac{v^2}{gR} \right).$$

The pressure on the bridge is equal to N in magnitude but is directed downward.

Problem 97. A crank OA of length l (Fig. 242) rotates with a uniform angular velocity ω and translates the slotted bar K of weight P along slides $1, 1$. Neglecting friction, determine the pressure exerted by the slide block A on the slotted bar.

Solution. The position of the bar is specified by its coordinate $x = l \cos \varphi$. As $\varphi = \omega t$, the equation of motion of the slotted bar is

$$x = l \cos \omega t.$$

Eq. (5) for the motion of the bar in terms of its projection on the x axis gives $m\omega_x = Q_x$. But $\omega_x =$

$$= \frac{d^2 x}{dt^2} = -l\omega^2 \cos \omega t = -\omega^2 x; \text{ whence, as } Q_x = -Q,$$

$$-\frac{P}{g} \omega^2 x = -Q, \quad Q = \frac{P}{g} \omega^2 x.$$

Thus, the pressure of the slide block on the slotted bar is proportional to its distance x from O .

The examples show that the first problem of dynamics is fairly simple. If the acceleration of the moving particle is not given,

it can be determined by purely kinematic computations. Therefore, and also because of its practical importance, the second problem is considered the principal problem of dynamics.

Chapter 17

DIFFERENTIAL EQUATIONS OF MOTION FOR A PARTICLE AND THEIR INTEGRATION

104. Rectilinear Motion of a Particle. We know from kinematics that in rectilinear motion the velocity and acceleration of a particle are continuously directed along the same straight line. As the direction of acceleration is coincident with the direction of force, it follows that a free particle will move in a straight line whenever the force acting on it is of constant direction and the velocity at the initial moment is either zero or is collinear with the force.

Consider a particle moving rectilinearly under the action of an applied force $R = \sum F_k$. The position of the particle on its path is specified by its coordinate x (Fig. 243). In this case the principal problem of dynamics is, knowing R , to find the equation of motion of the particle $x = f(t)$. Eq. (3) gives the relation between x and R . Projecting both sides of the equation on axis Ox , we obtain

Fig. 243.

$$\text{or, as } w_x = \frac{d^2x}{dt^2}, \quad m w_x = R_x \equiv \sum F_{kx},$$

$$m \frac{d^2x}{dt^2} = \sum F_{kx}. \quad (6)$$

Eq. (6) is called *the differential equation of rectilinear motion of a particle**. It is often more convenient to replace Eq. (6) with two differential equations containing first derivatives:

$$m \frac{dv_x}{dt} = \sum F_{kx}, \quad (7)$$

$$\frac{dx}{dt} = v_x. \quad (7')$$

* This is a differential equation, as the required quantity x is under the derivative symbol. Eq. (6) can also be used to solve the first problem of dynamics: knowing the equation of motion $x = f(t)$ for a particle, to determine the applied force F_x .

Whenever the solution of a problem requires that the velocity be found as a function of the coordinate x instead of time t (or when the forces themselves depend on x), Eq. (7) is converted to the variable x . As $\frac{dv_x}{dt} = \frac{dv_x}{dx} \cdot \frac{dx}{dt} = \frac{dv_x}{dx} v_x$, Eq. (7) takes the form

$$mv_x \frac{dv_x}{dx} = \sum F_{kx}. \quad (8)$$

The principal problem of dynamics is, essentially, to develop the equation of motion $x=f(t)$ for a particle from the above equations, the forces being known. For this it is necessary to integrate the corresponding differential equation. In order to make clearer the nature of the mathematical problem, it should be recalled that the forces in the right side of Eq. (6) can depend on time t , on the position of the particle x , or on the velocity $v_x = \frac{dx}{dt}$ (see § 99). Consequently, in the general case Eq. (6) is, mathematically, a differential equation of the second order in the form

$$\frac{d^2x}{dt^2} = \Phi \left(t, x, \frac{dx}{dt} \right). \quad (9)$$

The equation can be solved for every specific problem after determining the form of its right-hand member, which depends on the applied forces. When Eq. (9) is integrated for a given problem, the general solution will include two constants of integration C_1 and C_2 , and the general form of the solution will be

$$x = f(t, C_1, C_2). \quad (10)$$

To solve a concrete problem, it is necessary to determine the values of the constants C_1 and C_2 . For this we introduce the so-called *initial conditions*.

Investigation of any motion begins from some specified instant called the *initial time* $t=0$, usually the moment when the motion under the action of the given forces starts. The position occupied by a particle at the initial time is called its *initial displacement*, and its velocity at that time is its *initial velocity* (a particle can have an initial velocity either because at time $t=0$ it was moving under no force or because up to time $t=0$ it was subjected to the action of some other forces). To solve the principal problem of dynamics we must know, besides the applied forces, the *initial conditions*, i.e., the position and velocity of the particle at the initial time.

In the case of rectilinear motion, the initial conditions are specified in the form

$$\text{at } t=0, \quad x=x_0, \quad v_x=v_0. \quad (11)$$

From the initial conditions we can determine the meaning of the constants C_1 and C_2 and develop finally the equation of motion for the particle in the form

$$x=f(t, x_0, v_0). \quad (12)$$

The following simple example will explain the above.

Let there be acting on a particle a force Q of constant magnitude and direction. Then Eq. (7) acquires the form

$$m \frac{dv_x}{dt} = Q_x.$$

As $Q_x = \text{const.}$, multiplying both members of the equation by dt and integrating, we obtain*

$$v_x = \frac{Q_x}{m} t + C_1. \quad (13)$$

Substituting the value of v_x into Eq. (7'), we have

$$\frac{dx}{dt} = \frac{Q_x}{m} t + C_1.$$

Multiplying through by dt and integrating once again, we obtain

$$x = \frac{1}{2} \frac{Q_x}{m} t^2 + C_1 t + C_2. \quad (14)$$

This is the general solution of Eq. (9) for the specific problem in the form given by Eq. (10).

Now let us determine the integration constants C_1 and C_2 , assuming for the specific problem the initial conditions given by (11). Solutions (13) and (14) must satisfy any moment of time, including $t=0$. Therefore, substituting zero for t in Eqs. (13) and (14), we should obtain v_0 and x_0 instead of v_x and x , i.e., we should have

$$v_0 = C_1, \quad x_0 = C_2.$$

These equations give the values of the constants C_1 and C_2 which satisfy the initial conditions of a given problem. Substituting these values into Eq. (14), we obtain finally the

* We assume that the constant of integration has been transposed from the left to the right and included in C_1 .

relevant equation of motion in the form expressed by Eq. (12):

$$x = x_0 + v_0 t + \frac{1}{2} \frac{Q_x}{m} t^2. \quad (15)$$

We see from Eq. (15) that a particle subjected to a constant force performs uniformly variable motion. This could have been foreseen; for, if $Q = \text{const.}$, $w = \text{const.}$, too. An example of this type of motion is the motion of a particle under the force of gravity, in which case in Eq. (15) $\frac{Q_x}{m} = g$ and axis Ox is directed vertically down.

105. Solution of Problems. The method of integrating the differential equations of motion can be used for solving any problem of dynamics involving variable forces acting on a particle (see § 99).

The solution includes the following operations:

1) Write the differential equation of motion. For this,

a. Choose an origin (usually coinciding with the initial position of the particle) and draw a coordinate axis along the line of motion, as a rule in the direction of motion; if, for the applied forces, a particle has a position of equilibrium, it is convenient to choose the origin to coincide with the position of static equilibrium.

b. Draw the moving particle in an arbitrary position (but such that $x > 0$ and $v_x > 0$; the latter condition is important when the applied forces include forces depending on velocity), and draw all the forces acting on the particle.

c. Compound the projections of all the forces on the coordinate axis and substitute the sum into the right side of the differential equation of motion. *It is important to express all the variable forces in terms of the quantities (t , x or v) on which they depend.*

2) Integrating the differential equation of motion. The integration is carried out according to the rules of higher mathematics, depending on the form of the obtained equation, i.e., on the form of the right-hand member of Eq. (9). When besides the constant forces there is only one variable force acting on a particle, the equation of rectilinear motion can generally be integrated by the method of separating the variables (see Problems 98-100). If only the velocity has to be determined, it is often possible to solve the problem by integrating only Eq. (7) or Eq. (8).

3) Determining the constants of integration. In order to determine the constants of integration, it is necessary

from the conditions of the problem to define the initial conditions in the form (11). The values of the constants are found from the initial conditions as shown in § 104, and they can be determined directly after each integration.

4) Determination of the required quantities and analysing the results obtained. In order to be able to analyse the solution and also to verify the dimensions the whole solution should be carried out in the most general form (in letter notation), inserting the numerical data only in the final results.

These general rules also hold good for curvilinear motion.

Let us consider three specific problems, in which the force depends on the time, the distance, and the velocity of the motion of the particle.

1. Force Depends on Time

Problem 98. A load of weight P starts moving from rest along a smooth horizontal plane under the action of a force R the magnitude of which increases in proportion to the time, the relation being $R = kt$. Develop the equation of motion for the load.

Solution. Place the origin O in the initial position of the load and direct the axis Ox in the direction of motion (see Fig. 243). Then the initial conditions are: at $t=0$, $x=0$ and $v_x=0$. Draw the load in an arbitrary position and the forces acting on it. We have $R_x = R = kt$, and Eq. (7) takes the form

$$\frac{P}{g} \frac{dv_x}{dt} = kt.$$

Multiplying through by dt , we immediately separate the variables and obtain

$$v_x = \frac{kg}{P} \frac{t^2}{2} + C_1.$$

Substituting the initial values into this equation, we find that $C_1 = 0$. Then, substituting $\frac{dx}{dt}$ for v_x , we have

$$\frac{dx}{dt} = \frac{kg}{2P} t^2.$$

Multiplying through by dt we again separate the variables and, integrating, we find

$$x = \frac{kg}{2P} \frac{t^3}{3} + C_2.$$

Substitution of the initial values gives $C_2 = 0$, and we obtain the equation of motion for the load in the form

$$x = \frac{kg}{6P} t^3.$$

Thus, the displacement of the load is proportional to the cube of the time.

2. Force Depends on Distance

Problem 99. Neglecting the resistance of the air, determine the time it would take a body to travel from end to end of a tunnel AB dug through the earth along a chord (Fig. 244). Assume the earth's radius to be $R = 6,370$ km.

Note. The theory of gravitation states that a body inside the earth is attracted towards the centre of the earth with a force F directly proportional to the distance r from the centre. Taking into account that, at $r = R$ (i.e., at the surface of the earth), force F is equal to the weight of the body ($F = mg$), we find that inside the earth

$$F = \frac{mg}{R} r,$$

where $r = MC$ is the distance of point M from the centre of the earth.

Solution. Place the origin O in the middle of the chord AB (where a body in the tunnel would be in equilibrium) and direct the axis Ox along OA . If we assume the chord to be of length $2a$, the initial conditions will be: at $t = 0$, $x = a$ and $v_x = 0$.

The forces acting on the body in an arbitrary position are F and N . Consequently,

$$\sum F_{kx} = -F \cos \alpha = -\frac{mg}{R} r \cos \alpha = -\frac{mg}{R} x,$$

as it is evident from the diagram that $r \cdot \cos \alpha = x$.

We see that the acting force depends on the coordinate x of point M . In order to separate the variables in the differential equation of motion, write it in the form (8). Then, eliminating m and introducing the quantity

$$\frac{g}{R} = k^2,$$

we obtain

$$v_x = \frac{dv_x}{dx} = -k^2 x.$$

Multiplying through by dx , we separate the variables and, integrating, obtain

$$\frac{v_x^2}{2} = k^2 \frac{x^2}{2} + C_1.$$

From the initial conditions, at $x = a$, $v_x = 0$; hence $C_1 = -\frac{1}{2} k^2 a^2$. Substituting this expression of C_1 , we have

$$v_x = \pm k \sqrt{a^2 - x^2}.$$

As in the investigated position the velocity is directed from M to O , $v_x < 0$, and the sign before the radical should be minus. Then, substituting $\frac{dx}{dt}$ for v_x , we have

$$\frac{dx}{dt} = -k \sqrt{a^2 - x^2}.$$

Fig. 244.

Separating the variables, we write the equation in the form

$$kdt = \frac{dx}{\sqrt{a^2 - x^2}},$$

and integrating, we obtain

$$kt = \arccos \frac{x}{a} + C_2.$$

Substituting the initial data (at $t=0$, $x=a$) in this equation, we find that $C_2=0$. The equation of motion for the body in the tunnel is

$$x = a \cos kt.$$

Thus, the body is in harmonic motion with an amplitude a .

Now let us determine the time t_1 when the body will reach the end B of the tunnel. At B the coordinate $x = -a$. Substituting this value in the equation of motion, we obtain $\cos kt_1 = -1$, whence $kt_1 = \pi$ and $t_1 = \frac{\pi}{k}$. But

we have assumed $k = \sqrt{\frac{g}{R}}$. Calculating, we find that the time of the motion through the tunnel, given the conditions of the problem, does not depend on the length of the tunnel and is always equal to

$$t_1 = \pi \sqrt{\frac{R}{g}} \approx 42 \text{ min } 11 \text{ sec.}$$

This extremely interesting result has given rise to a number of projects—so far utopian—of such a tunnel.

Let us also find the maximum velocity of the body. From the expression for v_x we see that $v = v_{\max}$ at $x=0$, i.e., at the origin O . The magnitude of the velocity is

$$v_{\max} = ka = a \sqrt{\frac{g}{R}}.$$

If, for example, $2a = 0.1R = 637 \text{ km}$, then $v_{\max} \approx 395 \text{ m/sec} = 1,422 \text{ km h.}$

The vibration of a particle under the action of a force proportional to the distance will be studied in greater detail in Chapter 21, where another method of integrating the differential equations of motion will be discussed.

3. Force Depends on Velocity

Problem 100. A boat of weight $P = 40 \text{ kg}$ is pushed and receives an initial velocity $v_0 = 0.5 \text{ m/sec}$. Assuming the resistance of the water at low velocities to be proportional to the first power of the velocity and changing according to the equation $R = \mu v$, where the factor $\mu = 0.93 \text{ kg}\cdot\text{sec/m}$, determine the time in which the velocity will drop by one-half and the distance the boat will travel in that time. Determine also the distance the boat will travel till it stops.

Solution. Let us choose the origin O to coincide with the initial position of the boat, pointing the axis Ox in the direction of the motion (Fig. 245). In this case the initial conditions will be: at $t=0$, $x=0$ and $v_x = v_0$.

Draw the boat in an arbitrary position with the acting forces P , N , and R .

Fig. 245.

Note. There are no other forces acting on the boat. The force which pushed the boat acted before the instant $t=0$. The result of its action is taken into account by stating the initial velocity v_0 imparted to the boat by the force (see § 104). To be quite sure about the forces actually acting on a body during its motion, always remember that a force is the result of the interaction of bodies. In the present case, the force P is the result of the action of the earth on the boat, while forces R and N are the results of the action of the water on the boat. No other material bodies act on the boat in its motion and, consequently, there are no other forces applied to it. Attention is drawn to this because it is often a cause of errors in problem solutions.

Calculating the projections of the acting forces, we find that

$$\sum F_{kx} = -R = -\mu v.$$

To determine the duration of the motion, we write differential equation (7). Noting that $v_x = v$, we have

$$\frac{P}{g} \frac{dv}{dt} = -\mu v.$$

Separating the variables, we obtain

$$\frac{dv}{v} = -\frac{\mu g}{P} dt,$$

whence, integrating, we have

$$\ln v = -\frac{\mu g}{P} t + C_1.$$

Substituting the initial values, we have $C_1 = \ln v_0$, and finally

$$t = \frac{P}{\mu g} \ln \frac{v_0}{v}. \quad (a)$$

The required time t_1 is determined by assuming $v = 0.5v_0$. We see that in this case the time does not depend on the value of v_0 . As $\ln 2 = 0.69$,

$$t_1 = \frac{P}{\mu g} \ln 2 \approx 3 \text{ sec.}$$

To determine the distance, it is best to write the differential equation of motion in the form (8), as it immediately establishes the relation between x and v^* . We thus obtain

$$\frac{P}{g} v \frac{dv}{dx} = -\mu v,$$

whence, eliminating v and separating the variables, we find

$$dv = -\frac{\mu g}{P} dx,$$

* The distance can also be found by rewriting Eq. (a) as an expression of the velocity v in terms of time t , and then substituting $\frac{dx}{dt}$ for v and integrating the new equation, but this solution is more involved.

and consequently

$$v = -\frac{\mu g}{P}x + C_1.$$

Since at $x=0$, the velocity $v=v_0$, then $C_1=v_0$, and finally

$$x = \frac{P}{\mu g}(v_0 - v). \quad (b)$$

Assuming $v=0.5v_0$, we find the required displacement:

$$x_1 = \frac{Pv_0}{2\mu g} \approx 1.1 \text{ m.}$$

To find the distance travelled by the boat till it stops, in equation (b) we assume $v=0$. Then $x_2 = \frac{Pv_0}{\mu g} = 2.2 \text{ m.}$

Determining the duration of the motion until complete rest, we find from equation (a) that at $v=0$, $t_2=\infty$. This means that, under the given law of resistance $R=\mu v$, the boat will approach its final position (specified by the coordinate x_2) asymptotically. Actually, the duration of the motion till complete rest is finite, as, with the decrease of velocity, the resistance equation changes and the dependence of v on t changes accordingly.

Another important example of motion under the action of a force depending on velocity is discussed in the next article.

106. Body Falling in a Resisting Medium (in Air). A body moving in some medium is subjected to a resistance, which depends on the shape and size of the body, its velocity, and the properties of the medium.

Experience shows that at velocities which are not very small and not approaching the velocity of sound, the resistance is proportional to the square of the velocity v and can be expressed by the formula*

$$R = \frac{1}{2} c_x \rho S v^2, \quad (16)$$

where ρ is the density of the medium (for water at 15°C and 760 mm pressure, $\rho = \frac{1}{8} \frac{\text{kg} \cdot \text{sec}^3}{\text{m}^4}$), $S \text{ m}^2$ is the area of the projection of the body on a plane perpendicular to the direction of motion (the middle section), and c_x is a dimensionless resistance factor depending on the shape of the body. For example, for a parachute $c_x=1.4$, for a sphere $c_x=0.5$, for highly streamlined spindle-shaped bodies $c_x < 0.03$.

Let us consider a problem of a body falling in the atmosphere from a low height in comparison with the earth's radius (low

* For fall in air, formula (16) holds good for velocities up to 300 m/sec.

enough to assume the weight P of the body and the density of the air ρ to be constant).

Directing the coordinate axis Ox vertically down (Fig. 246), let us investigate how the velocity of fall depends on the displacement x , assuming $v_0 = 0$.

The forces acting on the falling body are P and R ; consequently,

$$\sum F_{kx} = P - R = P - \frac{1}{2} c_x \rho S v^2.$$

In order to obtain directly the dependence of v on x , we write the differential equation of motion in the form (8). Then, taking into account that $v_x = v$, we have

$$\frac{P}{g} v \frac{dv}{dx} = P - \frac{1}{2} c_x \rho S v^2.$$

Introducing the expression

$$\frac{2P}{c_x \rho S} = a^2, \quad (17)$$

the previous equation takes the form

$$v \frac{dv}{dx} = g \left(1 - \frac{v^2}{a^2} \right)$$

or, after separating the variables,

$$-\frac{v dv}{a^2 - v^2} = -\frac{g}{a^2} dx.$$

Fig. 246.

Integrating through, we have

$$\ln(a^2 - v^2) = -2 \frac{g}{a^2} x + C_1.$$

According to the initial conditions, at $x=0$, the velocity $v=0$, consequently $C_1 = \ln a^2$. Substituting this value of C_1 , we obtain

$$\ln \frac{a^2 - v^2}{a^2} = -2 \frac{g}{a^2} x,$$

or

$$\frac{a^2 - v^2}{a^2} = e^{-2 \frac{g}{a^2} x},$$

and finally

$$v = a \sqrt{1 - e^{-2 \frac{g}{a^2} x}}. \quad (18)$$

Formula (18) gives the dependence of velocity on displacement for a body falling in the atmosphere.

As x increases, the quantity $e^{-\frac{g}{a^2}x}$ decreases, and tends to zero as $x \rightarrow \infty$. It follows, then, that the velocity of fall v increases as x increases, tending to a constant value a . This quantity is called the *limiting velocity of fall* and is denoted v_{lim} . From Eq. (17) we find that

$$v_{\text{lim}} = \sqrt{\frac{2P}{c_x \rho S}}. \quad (19)$$

Thus, at $v_0 = 0$, a body falling in air cannot exceed a limiting velocity v_{lim} . The greater the weight of a body and the smaller the values of c_x , ρ , and S , the greater the limiting velocity of fall.

Let us determine the speed with which the velocity of a falling body approaches its limiting value. For this see Table 1, which gives the dependence of $\frac{v}{v_{\text{lim}}}$ upon $\frac{g}{v_{\text{lim}}^2}x$, as calculated from Eq. (18).

Table 1

$\frac{g}{v_{\text{lim}}^2}x$	$\frac{v}{v_{\text{lim}}}$
0	0
0.5	0.80
1.0	0.93
1.2	0.95
1.5	0.97
2.0	0.99

It follows from the table that

$$\left. \begin{array}{l} \text{at } \frac{g}{v_{\text{lim}}^2}x = 1.2, \quad v = 0.95v_{\text{lim}} \\ \text{at } \frac{g}{v_{\text{lim}}^2}x = 2.0, \quad v = 0.99v_{\text{lim}} \end{array} \right\} \quad (20)$$

Consequently, the velocity of fall approaches its limiting value fairly rapidly, if only the quantities c_x and S are not very small (see Problem 101).

The existence of a limiting velocity of fall can be established by the following simple reasoning: The velocity of a falling body in air increases, consequently force R increases. If we consider that, obviously, force R cannot be greater than the weight of the body P (see Fig. 246), then $R_{\text{lim}} = P$. Substituting the expression for R_{lim} from Eq. (16), we obtain $\frac{1}{2}c_x \rho S v_{\text{lim}}^2 = P$, whence we obtain the value of v_{lim} as in Eq. (19). This reasoning, however, provides no clue to the rate with which the velocity of fall v tends towards v_{lim} . This important characteristic can be obtained only from Eq. (18).

Problem 101. Determine the limiting velocity of fall of a parachute jumper weighing $P = 75$ kg (weight of parachute included), a) in free fall, assuming $S = 0.4$ m², $c_x = 1.0$; b) with open canopy, assuming $S = 36$ m², $c_x = 1.4$.

Determine for both cases the distance H_1 after which the jumper will have attained a velocity $v_1 = 0.95 v_{\text{lim}}$ (i.e., 5 per cent less than the limiting velocity), and the distance H_2 at which his velocity of fall $v_2 = 0.99 v_{\text{lim}}$.

Solution. Determine the limiting velocity of fall from Eq. (19), assuming for air $\rho = \frac{1}{8} \frac{\text{kg} \cdot \text{sec}^2}{\text{m}^3}$. We find H_1 and H_2 from Eq. (20). As $v_1 = 0.95 v_{\text{lim}}$

at $\frac{g}{v_{\text{lim}}^2} x = 1.2$, the required distance $H_1 = 1.2 \frac{v_{\text{lim}}^2}{g}$. Similarly we find that

$$H_2 = 2 \frac{v_{\text{lim}}^2}{g}.$$

Performing the necessary computations, we find:

a) in free fall $v_{\text{lim}} \approx 55$ m/sec, $H_1 \approx 370$ m, $H_2 \approx 610$ m.

b) with open canopy $v_{\text{lim}} \approx 5$ m/sec, $H_1 \approx 3$ m, $H_2 \approx 5$ m.

We see that when the resistance is great the limiting velocity is rapidly achieved.

107. Curvilinear Motion of a Particle. Consider a free particle moving under the action of forces F_1, F_2, \dots, F_n . Let us draw a fixed set of axes $Oxyz$ (Fig. 247). Projecting both members of the equation $m\mathbf{w} = \sum \mathbf{F}_k$ on these axes, and taking into account that $w_x = \frac{d^2x}{dt^2}$, etc., we obtain the differential equations of curvilinear motion of a body in terms of the projections on rectangular cartesian axes:

Fig. 247.

$$\begin{aligned} m \frac{d^2x}{dt^2} &= \sum F_{kx}, & m \frac{d^2y}{dt^2} &= \sum F_{ky}, \\ m \frac{d^2z}{dt^2} &= \sum F_{kz}. \end{aligned} \quad (21)$$

As the forces acting on the particle may depend on time, the displacement or the velocity of the particle, then by analogy with Eq. (9) in § 104, the right-hand members of Eq. (21) may contain the time t , the coordinates x, y, z of the particle, and the projections of its velocity $\frac{dx}{dt}, \frac{dy}{dt}, \frac{dz}{dt}$. Furthermore, the right side of each equation may include all these variables.

Eq. (21) can be used to solve both the first and the second (the principal) problems of dynamics. To solve the principal problem of dynamics we must know, besides the acting forces, the initial conditions, i.e., the position and velocity of the particle at the initial time. The initial conditions for a set of coordinate axes $Oxyz$ are specified in the form:

at $t=0$,

$$\left. \begin{aligned} x &= x_0, & y &= y_0, & z &= z_0 \\ v_x &= v_{x0}, & v_y &= v_{y0}, & v_z &= v_{z0} \end{aligned} \right\} \quad (22)$$

Knowing the acting forces, by integrating Eq. (21) we find the coordinates x, y, z of the moving particle as functions of time t , i.e., the equation of motion for the particle. The solutions will contain six constants of integration C_1, C_2, \dots, C_6 , the values of which must be found from the initial conditions (22). An example of integrating Eqs. (21) is given in § 108.

Differential equations of motion can also be written in terms of projections on other coordinate systems as, for instance, in § 117.

108. Motion of a Particle Thrown at an Angle to the Horizon in a Uniform Gravitational Field. Let us investigate the motion of a projectile thrown with an initial velocity v_0 at an angle α to the horizon, considering it as a material particle of mass m , neglecting the resistance of the atmosphere, assuming that the horizontal range is small as compared with the radius of the earth and considering the gravitational field to be uniform ($P = \text{const.}$).

Place the origin of the coordinate axes O at the initial position of the particle, direct the y axis vertically up, the x axis in the plane through Oy and vector \mathbf{v}_0 , and the z axis perpendicular to the first two (Fig. 248). The angle between vector \mathbf{v}_0 and the x axis will be α .

Draw now moving particle M anywhere on its path. Acting on the particle is only the force of gravity \mathbf{P} (see note to Problem 100, p. 240), the projections of which on the coordinate axes are

$$P_x = 0, \quad P_y = -P = -mg, \quad P_z = 0.$$

Substituting these values into Eq. (21) and noting that $\frac{d^2x}{dt^2} = \frac{dv_x}{dt}$, etc., after eliminating m we obtain

$$\frac{dv_x}{dt} = 0, \quad \frac{dv_y}{dt} = -g, \quad \frac{dv_z}{dt} = 0.$$

Multiplying these equations by dt and integrating, we find

$$v_x = C_1, \quad v_y = -gt + C_2, \quad v_z = C_3.$$

The initial conditions of our problem have the form

$$\begin{aligned} \text{at } t=0, \quad x=0, \quad y=0, \quad z=0; \\ v_x = v_0 \cos \alpha, \quad v_y = v_0 \sin \alpha, \quad v_z = 0. \end{aligned}$$

Fig. 248.

Satisfying the initial conditions, we have

$$C_1 = v_0 \cos \alpha, \quad C_2 = v_0 \sin \alpha, \quad C_3 = 0.$$

Substituting these values of C_1 , C_2 , and C_3 in the solutions above and replacing v_x , v_y , v_z by $\frac{dx}{dt}$, $\frac{dy}{dt}$, $\frac{dz}{dt}$, we arrive at the equations

$$\frac{dx}{dt} = v_0 \cos \alpha, \quad \frac{dy}{dt} = v_0 \sin \alpha - gt, \quad \frac{dz}{dt} = 0.$$

Integrating, we obtain

$$x = v_0 t \cos \alpha + C_4, \quad y = v_0 t \sin \alpha - \frac{gt^2}{2} + C_5, \quad z = C_6.$$

Substituting the initial conditions, we have $C_1 = C_2 = C_3 = 0$. And finally we obtain the equations of motion of particle M in the form

$$x = v_0 t \cos \alpha, \quad y = v_0 t \sin \alpha - \frac{gt^2}{2}, \quad z = 0. \quad (23)$$

From the last equation it follows that the motion takes place in the plane Oxy .

Knowing the equations of motion of a particle it is possible to determine all the characteristics of the given motion by the methods of kinematics.

1. **Path.** Eliminating the time t between the first two of Eqs. (23), we obtain the equation of the path of the particle:

$$y = x \tan \alpha - \frac{gx^2}{2v_0^2 \cos^2 \alpha}. \quad (24)$$

This is an equation of a parabola the axis of which is parallel to the y axis. Thus, *a heavy particle thrown at an angle to the horizon in vacuo follows a parabolic path* (Galileo).

2. **Horizontal Range.** The horizontal range is the distance $OC = X$ along the x axis. Assuming in Eq. (24) $y = 0$, we obtain the points of intersection of the path with the x axis. From the equation

$$x \left(\tan \alpha - \frac{gx}{2v_0^2 \cos^2 \alpha} \right) = 0$$

we obtain

$$x_1 = 0, \quad x_2 = \frac{2v_0^2 \cos^2 \alpha \tan \alpha}{g}.$$

The first solution gives point O , the second point C . Consequently $X = x_2$, and finally

$$X = \frac{v_0^2}{g} \sin 2\alpha. \quad (25)$$

From Eq. (25) we see that the horizontal range X is the same for angle β , where $2\beta = 180^\circ - 2\alpha$, i.e., if $\beta = 90^\circ - \alpha$. Consequently, a particle thrown with a given initial velocity v_0 can reach the same point C by two paths: flat (low) ($\alpha < 45^\circ$) or curved (high) ($\beta = 90^\circ - \alpha > 45^\circ$).

With a given initial velocity v_0 , the maximum horizontal range in vacuo is obtained when $\sin 2\alpha = 1$, i.e., when angle $\alpha = 45^\circ$.

3. Height of path. If in Eq. (24) we assume $x = \frac{1}{2}X = \frac{v_0^2}{g} \sin \alpha \cos \alpha$, we obtain the height H of the path:

$$H = \frac{v_0^2}{2g} \sin^2 \alpha. \quad (26)$$

4. Time of flight. It follows from Eq. (23) that the total time of flight is defined by the equation $X = v_0 T \cos \alpha$. Substituting the expression for X , we obtain

$$T = \frac{2v_0}{g} \sin \alpha. \quad (27)$$

At the maximum range angle $\alpha^* = 45^\circ$, all the quantities become respectively

$$X^* = \frac{v_0^2}{g}, \quad H^* = \frac{v_0^2}{4g} = \frac{1}{4} X^*, \quad T^* = \frac{v_0}{g} \sqrt{2}. \quad (28)$$

These results can be used to estimate the flight characteristics of missiles (rockets) with a horizontal range of 200 to 600 km, as at such ranges (and at $\alpha \approx 45^\circ$) a projectile travels most of its path in the stratosphere, where atmospheric resistance can be neglected. At closer ranges the resistance of the air has a considerable effect, while at ranges exceeding 600 km the gravitational force can no longer be considered constant.

Example. It is known that at an altitude of 20 km a vertically launched German V-2 rocket had a velocity $v_0 \approx 1,700$ m/sec and an angle $\alpha \approx 45^\circ$ (the rocket was inclined by means of special instruments and control vanes). The further flight of the rocket was actually motion of a projectile in vacuo. Therefore, from Eqs. (28), its characteristics must have been

$$X^* \approx 300 \text{ km}, \quad H^* \approx 75 \text{ km}, \quad T^* \approx 245 \text{ sec.}$$

These results are very close to the actual performance of V-2 rockets*.

Chapter 18

GENERAL THEOREMS OF PARTICLE DYNAMICS

In solving many problems of dynamics it will be found that the so-called *general theorems*, representing corollaries of the fundamental law of dynamics, are more conveniently applied than the method of integration of differential equations of motion.

The importance of the general theorems is that they establish visual relationships between the principal dynamic characteristics of motion of material bodies, thereby presenting broad possibilities for analysing the mechanical motions widely employed in practical engineering. Furthermore, the general theorems make it possible to study for practical purposes specific aspects of a given phenomenon without investigating the phenomenon as a whole. Finally, the use of the general theorems makes it unnecessary to carry out for every problem the operations of integration performed once and for all in proving the theorems, which simplifies the solution.

109. Momentum and Kinetic Energy of a Particle. The basic dynamic characteristics of particle motion are *momentum* (or linear momentum) and *kinetic energy*.

The momentum of a particle is defined as a vector quantity $m\mathbf{v}$ equal to the product of the mass of the particle and its velocity. The vector $m\mathbf{v}$ is directed in the same direction as the velocity, i.e., tangent to the path of the particle.

The kinetic energy of a particle is defined as a scalar quantity equal to half the product of the mass of the particle and the square of its velocity $\left(\frac{1}{2}mv^2\right)$.

The dimensions of these quantities in the technical system of units are

$$[m\mathbf{v}] = \frac{\text{kg sec}^2}{\text{m}} \cdot \frac{\text{m}}{\text{sec}} = \text{kg-sec}; \quad \left[\frac{mv^2}{2}\right] = \frac{\text{kg sec}^2}{\text{m}} \cdot \frac{\text{m}^2}{\text{sec}^2} = \text{kg-m}.$$

The reason for the introduction of two dynamic characteristics is that a single characteristic does not cover all the aspects of particle motion.

For example, knowing the momentum of a motor car (i.e., the quantity $q = mv$, but not the separate values of m and v) and the force acting on it when it brakes, we can determine the time it will take for the car to stop; the information, however, is not enough to determine the path travelled during the braking time. Conversely, knowing the initial kinetic energy of

the car and the braking force, we can determine the braking distance, but not the time of the braking*.

110. Impulse of a Force. The concept of *impulse* (or linear impulse) of a force is used to characterise the effect on a body of a force acting during a certain interval of time. First let us introduce the concept of elementary impulse, i.e., impulse in an infinitesimal time interval dt . *Elementary impulse is defined as a vector quantity $d\mathbf{S}$ equal to the product of the vector of the force \mathbf{F} and the time element dt :*

$$d\mathbf{S} = \mathbf{F} dt. \quad (29)$$

The elementary impulse is directed along the action line of the force.

The impulse \mathbf{S} of any force \mathbf{F} during a finite time interval t_1 is computed as the integral sum of the respective elementary impulses:

$$\mathbf{S} = \int_0^{t_1} \mathbf{F} dt. \quad (30)$$

Thus, the impulse of a force in any time interval t_1 is equal to the integral of the elementary impulse over the interval from zero to t_1 .

In the special case when the force \mathbf{F} is of constant magnitude and direction ($\mathbf{F} = \text{const.}$), we have $\mathbf{S} = \mathbf{F}t_1$. In the general case the magnitude of an impulse can be computed from its projections.

We can find the projections of an impulse on a set of coordinate axes if we remember that an integral is the limit of a sum, and the projection of a vector sum on an axis is equal to the sum of the projections of the component vectors on the same axis. Hence,

$$S_x = \int_0^{t_1} F_x dt, \quad S_y = \int_0^{t_1} F_y dt, \quad S_z = \int_0^{t_1} F_z dt. \quad (31)$$

With these projections we can construct the vector \mathbf{S} and find its magnitude and the angles it makes with the coordinate axes. The dimension of linear impulse in the technical system of units is $[\mathbf{S}] = \text{kg-sec}$.

To solve the principal problem of dynamics, it is important to establish the forces whose impulses can be computed *without knowing the equation of motion* of the particle moving under the action of those forces. From Eq. (31) it is apparent that to these forces belong only *constant forces and forces depending on time*.

* See Problem 103 (§ 115).

In order to calculate the impulses of forces depending on the coordinates or the velocity of a particle, we have to know the equations of its motion, i.e., $x=f_1(t)$, $y=f_2(t)$, $z=f_3(t)$. By expressing x , y , z or v_x , v_y , v_z through t , we can compute the integrals (31). Without knowing the equation of motion of a particle, i.e., without first solving the principal problem of dynamics, the impulse of such forces cannot be calculated.

111. Theorem of the Change in the Momentum of a Particle. As the mass of a particle is constant, and its acceleration $\mathbf{w} = \frac{d\mathbf{v}}{dt}$, equation (3), which expresses the fundamental law of dynamics, can be expressed in the form

$$\frac{d(m\mathbf{v})}{dt} = \sum \mathbf{F}_k. \quad (32)$$

Let a particle of mass m moving under the action of a force $\mathbf{R} = \sum \mathbf{F}_k$ (Fig. 249a) have a velocity \mathbf{v}_0 at time $t=0$, and at time t_1 let its velocity be \mathbf{v}_1 . Now let us multiply both sides

of Eq. (32) by dt and take definite integrals. On the right side, where we integrate with respect to time, the limits of the integrals are zero and t_1 ; on the left side, where we integrate the velocity, the limits of the integral are the respective values of \mathbf{v}_0 and \mathbf{v}_1 . As the integral of $d(m\mathbf{v})$ is $m\mathbf{v}$, we have

$$m\mathbf{v}_1 - m\mathbf{v}_0 = \sum \int_0^{t_1} \mathbf{F}_k dt.$$

By Eq. (30), the integrals on the right side are the impulses of the acting force. Hence, we finally have

$$m\mathbf{v}_1 - m\mathbf{v}_0 = \sum \mathbf{S}_k. \quad (33)$$

Eq. (33) states the theorem of the change in the linear momentum of a particle: *The change in the momentum of a particle during any time interval is equal to the geometric sum of the impulses of all the forces acting on the particle during that interval of time* (Fig. 249b).

In problem solutions, projection equations are often used instead of the vector equation (33). Projecting both sides of Eq.

Fig. 249.

(33) on a set of coordinate axes, we have

$$\left. \begin{aligned} mv_{1x} - mv_{0x} &= \sum S_{kx}, \\ mv_{1y} - mv_{0y} &= \sum S_{ky}, \\ mv_{1z} - mv_{0z} &= \sum S_{kz}. \end{aligned} \right\} \quad (34)$$

In the case of rectilinear motion along the x axis, the theorem is stated by the first of these equations.

112. Work Done by a Force. Power. The concept of work is introduced as a measure of the action of a force on a body in a given displacement, specifically that action which is represented by the change in the *magnitude* of the velocity of a moving particle.

First let us introduce the concept of elementary work done by a force in an infinitesimal displacement ds . The elementary work done by a force \mathbf{F} (Fig. 250) is defined as a scalar quantity

$$dA = F_{\tau} ds, \quad (35)$$

where F_{τ} is the projection of the force on the tangent to the path in the direction of the displacement, and ds is an infinitesimal displacement of the particle along that tangent.

This definition corresponds to the concept of work as a characteristic of that action of a force which tends to change the magnitude of velocity. For if force \mathbf{F} is resolved into components \mathbf{F}_{τ} and \mathbf{F}_n , only the component \mathbf{F}_{τ} , which imparts the particle its tangential acceleration, will change the magnitude of the velocity. As for component \mathbf{F}_n , it either changes the direction of the velocity vector \mathbf{v} (gives the particle its normal acceleration) or, in the case of constrained motion, changes the pressure on the constraint. Component \mathbf{F}_n does not affect the magnitude of the velocity, or, as they say, force \mathbf{F}_n "does no work".

Noting that $F_{\tau} = F \cos \alpha$, we further obtain from Eq. (35)

$$dA = F ds \cos \alpha. \quad (36)$$

Thus, the elementary work done by a force is equal to the product of the projection of that force on the direction of displacement of the particle and the infinitesimal displacement ds (Eq. 35) or, the elementary work done by a force is the product of the magnitude of that force, the infinitesimal displacement ds , and the cosine of the angle between the direction of the force and the direction of the displacement (Eq. 36).

Fig. 250.

If angle α is acute, the work is of positive sense. In particular, at $\alpha=0$, the elementary work $dA=F ds$.

If angle α is obtuse, the work is of negative sense. In particular, at $\alpha=180^\circ$, the elementary work $dA=-F ds$.

If angle $\alpha=90^\circ$, i.e., if a force is directed perpendicular to the displacement, the elementary work done by the force is zero.

The sign of the work has the following meaning: the work is positive when the tangential component of the force is pointed in the direction of the displacement, i.e., when the force accelerates the motion; the work is negative when the tangential component is pointed opposite the displacement, i.e., when the force retards the motion.

Fig. 251.

Let us now find an analytical expression for elementary work. For this we resolve force F into components F_x , F_y , F_z parallel to the coordinate axes (Fig. 251; the force F is not shown in the diagram). The infinitesimal displacement $MM'=ds$ is compounded of the displacements dx , dy , dz parallel to the coordinate axes, where x , y , z are the

coordinates of point M . The work done by force F in the displacement ds can be calculated as the sum of the work done by its components F_x , F_y , F_z in the displacements dx , dy , dz . But the work in the displacement dx is done only by component F_x and is equal to $F_x dx$. The work in the displacements dy and dz is calculated similarly. Thus, we finally obtain

$$dA = F_x dx + F_y dy + F_z dz. \quad (37)$$

Eq. (37) gives the analytical expression of the elementary work done by a force.

The work done by a force in any finite displacement $M_0 M_1$ (see Fig. 250) is calculated as the integral sum of the corresponding elementary works and is equal to

$$A_{(M_0 M_1)} = \int_{(M_0)}^{(M_1)} F_\tau ds, \quad (38)$$

or

$$A_{(M_0 M_1)} = \int_{(M_0)}^{(M_1)} (F_x dx + F_y dy + F_z dz). \quad (38')$$

Thus, the work done by a force in any displacement $M_0 M_1$ is equal to the integral of the elementary work taken along this

displacement. The limits of the integral correspond to the values of the variables of integration at points M_0 and M_1 (or, more exactly, the integral is taken along the curve M_0M_1 , i.e., it is curvilinear).

If the quantity F_r is constant ($F_r = \text{const.}$), then from Eq. (38), denoting the displacement $\widetilde{M_0M_1}$ by the symbol s_1 , we obtain

$$A_{(M_0M_1)} = F_r s_1. \quad (38'')$$

In particular, such a case is possible when the acting force is constant in magnitude and direction ($F = \text{const.}$) and the point of application is in rectilinear motion (Fig. 252). In this case $F_r = F \cos \alpha = \text{const.}$, and the work done by the force $A_{(M_0M_1)} = F s_1 \cos \alpha$.

Fig. 252.

In order to solve the principal problem of dynamics, it is important to establish the forces whose work can be calculated immediately without knowing the equation of motion of the particle on which they are acting (compare with § 110). From Eq. (38') it can be seen that to these forces belong *only constant forces or forces which depend on the position (coordinates) of a moving particle*.

Fig. 253.

motion of the particle, i.e., without first solving the principal problem of dynamics, the work done by such forces cannot be determined.

Graphical Method of Calculating Work. If a force depends on the displacement s and a graph is given showing the dependence of F_r on s (Fig. 253), the work done by a force F can be calculated graphically. Let a particle at M_0 be at a distance s_0 from the origin, and at M_1 let its displacement be s_1 . Then, from Eq. (38), taking into account the geometric interpretation of integration, we have

$$A_{(M_1M_0)} = \int_{s_0}^{s_1} F_r ds = \sigma,$$

where σ is the product of the shaded area in Fig. 253 and a scale factor.

Power. The term *power* is defined as the work done by a force in a unit of time (the time rate of doing work). If work is done at a constant rate, the power

$$W = \frac{A}{t_1},$$

where t_1 is the time in which the work A is done. In the general case,

$$W = \frac{dA}{dt} = \frac{F_z ds}{dt} = F_z v.$$

Thus, power is the product of the tangential component of a force and the velocity. The dimension of power in the technical system of units is $[W] = \text{kg-m/sec}$.

In engineering the unit of power commonly used is the horsepower, which is equal to 75 kg-m/sec. In the physical system power is expressed in kilowatts, one hp being equal to 0.736 kw.

The work done by a machine can be expressed as the product of its power and the time of work. This has given rise to the commonly used technical unit of work, the kilowatt-hour ($1 \text{ kw-h} \approx 367,100 \text{ kgm}$).

It can be seen from the equation $W = F_z v$ that if a motor has a given power W , the tractive force F_z is inversely proportional to the velocity v . That is why, for instance, on an upgrade or poor road a motor car goes into lower gear, thereby reducing the speed and developing a greater tractive force with the same power.

Fig. 254.

113. Examples of Calculation of Work. The examples considered below give results which can be used immediately in solving problems.

1) Work Done by a Gravitational Force. Let a particle

M subjected to a gravitational force P be moving from a point $M_0(x_0, y_0, z_0)$ to a point $M_1(x_1, y_1, z_1)$. Choose a coordinate system so that the axis Oz would point vertically up (Fig. 254). Then $P_x = 0$, $P_y = 0$, $P_z = -P$. Substituting these expressions into Eq. (38') and taking into account that the integration variable is z , we obtain

$$A_{(M_0 M_1)} = \int_{(M_0)}^{(M_1)} (-P dz) = -P \int_{z_0}^{z_1} dz = P(z_0 - z_1).$$

If point M_0 is higher than M_1 , then $z_0 - z_1 = h$, where h is the vertical displacement of the particle; if, on the other hand, M_0 is below M_1 , then $z_0 - z_1 = -(z_1 - z_0) = -h$. Finally we have

$$A_{(M_0 M_1)} = \pm Ph. \quad (39)$$

Thus, the work done by a gravitational force is equal to the product of the magnitude of the force and the vertical displacement of the point to which it is applied, taken with the appropriate sign.

The work is positive if the initial point is higher than the final one and negative if it is lower.

It follows from this that the work done by gravity does not depend on the path along which the point of its application moves. Forces possessing this property are called *conservative forces*.

Fig. 255.

2) Work Done by an Elastic Force. Consider a weight M lying in a horizontal plane and attached to the free end of a spring (Fig. 255a). Let point O on the plane represent the position of the end of the spring when it is not in tension ($AO = l_0$ is the length of the unextended spring) and let it be the origin of our coordinate system. Now if we draw the weight from its position of equilibrium O , stretching the spring to length l , acting on the weight will be the elastic force of the spring F directed towards O . According to Hooke's Law, the magnitude of this force is proportional to the extension of the spring $\Delta l = l - l_0$. As in our case $\Delta l = x$, then in magnitude

$$F = c |\Delta l| = c |x|.$$

The factor c is called the *stiffness* of the spring, or the spring constant, and its dimension is $[c] = \text{kg/cm}$. Numerically, the stiffness c is equal to the force required to extend the spring by 1 cm.

Let us find the work done by the elastic force in the displacement of the weight from position $M_0(x_0)$ to position $M_1(x_1)$. As in this case $F_x = -F = -cx$, $F_y = F_z = 0$, then, substituting these expressions into Eq. (38'), we obtain

$$A_{(M_0 M_1)} = \int_{(M_0)}^{(M_1)} (-cx) dx = -c \int_{x_0}^{x_1} x dx = \frac{c}{2} (x_0^2 - x_1^2).$$

(The same result could be obtained from the graph of F depending

on x (Fig. 255b) by calculating the area σ of the shaded trapezium in the diagram and taking into account the sign of the work.) In the obtained formula x_0 is the initial extension of the spring Δl_{in} , and x_1 is the final extension Δl_{fin} . Hence

$$A_{(M_0 M_1)} = \frac{c}{2} [(\Delta l_{in})^2 - (\Delta l_{fin})^2], \quad (40)$$

i.e., the work done by an elastic force is equal to half the product of the stiffness and the difference between the squares of the initial and final extensions (or compressions) of a spring.

The work is positive if $|\Delta l_{in}| > |\Delta l_{fin}|$, i.e., when the end of the spring moves towards the position of equilibrium, and negative when $|\Delta l_{in}| < |\Delta l_{fin}|$, i.e., when the end of the spring moves away from the position of equilibrium.

Fig. 256.

It can be proved that Eq. (40) holds good for the case when the displacement of point M is not rectilinear. It follows, therefore, that the work done by the force F depends only on the quantities Δl_{in} and Δl_{fin} and does not depend on the actual path travelled by M . Consequently, an elastic force is also a *conservative force*.

3) Work Done by Friction. Consider a particle moving on a rough surface (Fig. 256) or a rough curve. The magnitude of the frictional force acting on the particle is fN , where f is the coefficient of friction and N is the normal reaction of the surface. Frictional force is directed opposite to the displacement of the particle, whence $F_{fr} = -fN$, and from Eq. (38),

$$A_{(M_0 M_1)} = - \int_{(M_0)}^{(M_1)} F_{fr} ds = - \int_{(M_0)}^{(M_1)} fN ds.$$

If the frictional force is constant, then $A_{(M_0 M_1)} = -F_{fr}s$, where s is the length of the arc $M_0 M_1$ along which the particle moves.

Thus, the work done by kinetic friction is always negative. It depends on the length of the arc $M_0 M_1$, and consequently it is *non-conservative*.

114. Theorem of the Change in the Kinetic Energy of a Particle. Consider a particle of mass m displaced by acting forces from a position M_0 where its velocity is v_0 to a position M_1 where its velocity is v_1 .

To obtain the required relation, consider the equation $m\mathbf{w} = \sum \mathbf{F}_k$, which expresses the fundamental law of dynamics. Projecting

both parts of this equation on the tangent $M\tau$ to the path of the particle in the direction of motion, we obtain

$$m\omega_\tau = \sum F_{k\tau}.$$

The tangential acceleration in the left side of the equation can be written in the form

$$\omega_\tau = \frac{dv}{dt} = \frac{dv}{ds} \frac{ds}{dt} = \frac{dv}{ds} v,$$

whence we have

$$m\omega \frac{dv}{ds} = \sum F_{k\tau}.$$

Multiplying both sides of the equation by ds , bring m under the differential sign. Then, noting that $F_{k\tau} ds = dA_k$, where dA_k is the elementary work done by the force F_k , we obtain an expression of the theorem of the change in kinetic energy in differential form:

$$d\left(\frac{mv^2}{2}\right) = \sum dA_k. \quad (41)$$

Integrating both sides of Eq. (41) in the limits between the corresponding values of the variables at points M_0 and M_1 , we finally obtain

$$\frac{mv_1^2}{2} - \frac{mv_0^2}{2} = \sum A_{(M_0, M_1)}. \quad (42)$$

Eq. (42) states the theorem of the change in the kinetic energy of a particle in the final form: *The change in the kinetic energy of a particle in any displacement is equal to the algebraic sum of the work done by all the forces acting on the particle in the same displacement.*

The Case of Constrained Motion. If the motion of a particle is constrained, then, from Eq. (5), the left side of Eq. (42) will include the work done by the given (active) forces F_k^a and the work done by the reaction force of the constraint. Let us limit ourselves to the case of a particle moving on a fixed smooth (frictionless) surface or curve. In this case the reaction N (see Fig. 256) is normal to the path of the particle, and $N_\tau = 0$. Then by Eq. (38), the work done by the reaction force of a fixed smooth surface (or curve) in any displacement of a particle is zero, and from Eq. (42) we obtain

$$\frac{mv_1^2}{2} - \frac{mv_0^2}{2} = \sum A_{(M_0, M_1)}^a. \quad (42')$$

Thus, in a displacement of a particle on a fixed smooth surface (or curve) the change in the kinetic energy of the particle is equal to the sum of the work done in this displacement by the active forces applied to that particle.

If the surface (curve) is not smooth, the work done by frictional force will be added to the work done by the active forces (see § 113). If the surface (curve) is itself in motion, the absolute displacement of the particle M may not be perpendicular to N and the work done by the reaction N will not be zero (for instance, the work done by the reaction of the floor of a lift).

115. Solution of Problems. The first thing in approaching any problem is to see whether one of the above theorems can be directly applied to solve it. The following considerations should be borne in mind.

The theorem of the change in the linear momentum of a particle is conveniently used to solve problems in which:

- a) the acting forces are *constant* or depend only on the *time*;
- b) the given and required quantities include the acting forces, the *duration of the motion*, and the initial and final velocity of the particle (i.e., F , t , v_0 , and v_1).

The theorem of the change in the kinetic energy of a particle is conveniently used to solve problems in which:

- a) the acting forces are *constant* or depend only on the *distance*;
- b) the given and required quantities include the acting forces, the *displacement of the particle*, and the velocity at the beginning and the end of the displacement (i.e., F , s , v_0 , and v_1).

Both theorems can be combined to solve problems in which both the time of motion and the displacement of a particle are given (or required).

If the acting forces include a force depending on the velocity, the principal problem of dynamics cannot be solved with the help of any of the general theorems (it is impossible immediately to calculate the work done by, or the impulse of, a force). In this case the method of integration of differential equations should be used (Chapter 17).

The following steps for the solution may be suggested:

1. From the statement of the problem determine the theorem which can be used for its solution.

2. Draw the moving particle in an arbitrary position together with all the active forces and the reactions of the constraints (in the case of constrained motion).

3. Calculate with the corresponding formulas the impulses or work done by all the forces during the motion.

4. Applying Eq. (34) or (42), write the appropriate equations and find the required quantities. In the computations special attention should be paid to expressing all the quantities in the same system of units.

The theorems proved above are also convenient to determine the impulses or the work done by the forces acting on a particle from the change in its momentum or kinetic energy (the first problem of dynamics).

Problem 102. A load of weight $p = 0.1$ kg moves in a circle with a constant velocity $v = 2$ m/sec. Determine the impulse and the work done by the force acting on the load during the time the load takes to travel one quarter of the circle.

Solution. From the theorem of the change in momentum,

$$S = mv_1 - mv_0.$$

Constructing geometrically the difference between these momenta (Fig. 257), we find from the right-angled triangle:

$$S = m\sqrt{v_1^2 + v_0^2}.$$

Fig. 257.

But from the conditions of the problem $v_1 = v_0 = v$, consequently

$$S = \frac{p}{g} v \sqrt{2} = 0.029 \text{ kg-sec.}$$

From Eq. (42) we determine the work:

$$A_{(M_0 M_1)} = \frac{m}{2} (v_1^2 - v_0^2) = 0.$$

Problem 103. A load of mass m lying on a horizontal plane is pushed and imparted an initial velocity v_0 . The motion of the load is then retarded by a constant force F . Determine the time it takes the load to stop and how far it will have travelled.

Fig. 258.

Solution. From the conditions of the problem we see that the first of our theorems can be used to calculate the time of the motion and the second to determine the distance.

Draw the load in an arbitrary position M (Fig. 258), M_0 and M_1 being its initial and final positions. Acting on the load are its weight P , the reaction of the plane N , and the opposing force F . Pointing axis Ox in the direction of the motion, we have from Eq. (34):

$$mv_{1x} - mv_{0x} = \sum S_x.$$

In this case $v_{1x} = 0$ (v_1 is the velocity at the instant when the load stops) and $v_{0x} = v_0$. Force F is the only one projected on the x axis. As it is constant, $S_x = F_x t_1 = -F t_1$, where t_1 is the deceleration time. Substituting these expressions into our equation, we obtain $-mv_0 = -F t_1$, whence the required

time is

$$t_1 = \frac{mv_0}{F}. \quad (a)$$

To determine the braking distance we use the theorem of the change in kinetic energy:

$$\frac{mv_1^2}{2} - \frac{mv_0^2}{2} = \sum A(M_0 M_1).$$

Here again $v_1 = 0$ and only force F does any work: $A(F) = -Fs$, where s is the braking distance. The work done by forces P and N is zero as they are perpendicular to the displacement. Hence we obtain $-\frac{mv_0^2}{2} = -Fs_1$, and the braking distance is

$$s_1 = \frac{mv_0^2}{2F}. \quad (b)$$

We see from equations (a) and (b) that the braking time for a given force F is proportional to the initial velocity v_0 , and the braking distance is proportional to the square of the initial velocity.

If the braking force is a frictional force and the coefficient of friction f is known, then $F = fP = fmg$, and equations (a) and (b) give

$$t_1 = \frac{v_0}{fg}, \quad s_1 = \frac{v_0^2}{2fg}.$$

Note that if we were given the initial momentum $q_0 = mv_0$ (for example, $q_0 = 2$ kg-sec) instead of the mass m and initial velocity v_0 , knowing F we could find the braking time from equation (a), but the data would be insufficient to determine the braking distance s_1 .

Conversely, if we knew the initial kinetic energy of the load $T_0 = \frac{mv_0^2}{2}$ and the force F , we could determine the braking distance s_1 from formula (b), but we would not be able to determine the braking time t_1 . This was mentioned in § 109.

Problem 104. The resultant R of all the forces acting on the piston in Fig. 259 changes during a certain time-interval according to the equation $R = 0.4P(1 - kt)$, where P is the weight of the piston, t is the time in seconds, and k a factor equal to 1.6 sec^{-1} . Determine the velocity of the

piston at time $t_1 = 0.5$ sec, if at time $t_0 = 0$ it was $v_0 = 0.2$ m/sec.

Solution. As the acting force depends on the time and the given and required quantities include t_1 , v_0 , and v_1 , we make use of Eq. (34):

$$mv_{1x} - mv_{0x} = S_x.$$

In this case

$$S_x = \int_0^{t_1} R_x dt = 0.4P \int_0^{t_1} (1 - kt) dt = 0.4Pt_1 \left(1 - \frac{k}{2} t_1 \right).$$

Fig. 259.

Furthermore, $v_{0x} = v_0$, $v_{1x} = v_1$, $P = mg$. Substituting these expressions into Eq. (33) and taking into account that $k = 1.6 \text{ sec}^{-1}$ and $t_1 = 0.5 \text{ sec}$, we obtain

$$v_1 = v_0 + 0.4 g t_1 \left(1 - \frac{k}{2} t_1 \right) \approx 1.4 \text{ m/sec.}$$

Problem 105. A weight attached to a string of length l (Fig. 260 a) is displaced from the vertical at an angle φ_0 and released from rest. Determine the velocity of the weight at the instant when the thread makes an angle φ with the vertical.

Solution. As the conditions of the problem include the displacement of the weight, defined by the angle through which the thread passes, and the velocities v_0 and v_1 , we make use of the theorem of the change in kinetic energy:

$$\frac{mv_1^2}{2} - \frac{mv_0^2}{2} = \sum A_{(M_0 M_1)}.$$

Acting on the weight is the force of gravity P and the reaction of the thread N . The work done by force N is zero, as $N_\tau = 0$. For force P we have from Eq. (39): $A(P) = Ph = mgh$. As $v_0 = 0$, we obtain $\frac{mv_1^2}{2} = mgh$, whence

$$v_1 = \sqrt{2gh}.$$

This is the famous formula of Galileo. Evidently, the result is the same for the velocity v of a freely falling weight (Fig. 260b).

In our problem $h = l \cos \varphi - l \cos \varphi_0$, and finally

$$v = \sqrt{2gl(\cos \varphi - \cos \varphi_0)}.$$

Problem 106. The length l_0 of an uncompressed valve spring is 6 cm. When the valve is completely open it is lifted to a height $s = 0.6 \text{ cm}$ and the length of the compressed spring is $l = 4 \text{ cm}$ (Fig. 261). The stiffness of the spring is $c = 0.1 \text{ kg/cm}$ and the weight of the valve is $p = 0.4 \text{ kg}$. Neglecting the gravitational and resisting forces, determine the velocity of the valve at the moment of its closure.

Solution. The elastic force F acting on the valve depends on the displacement s of the valve, which is given. Therefore we use Eq. (42):

$$\frac{mv_1^2}{2} - \frac{mv_0^2}{2} = A_{(M_0 M_1)}.$$

According to the conditions of the problem, the only force doing work is the elastic force of the spring. Hence, from Eq. (40), we have

$$A_{(M_0 M_1)} = \frac{c}{2} [(\Delta l_{in})^2 - (\Delta l_{fin})^2].$$

Fig. 261.

Fig. 260.

In our case

$$\Delta l_{\text{in}} = l_0 - l = 2 \text{ cm}, \quad \Delta l_{\text{fin}} = l_0 - l - s = 1.4 \text{ cm}.$$

Furthermore, $v_0 = 0$ and $m = \frac{P}{g}$. Substituting these expressions into Eq. (42), we obtain

$$v_1 = \sqrt{\frac{cg}{\rho} (\Delta l_{\text{in}})^2 - (\Delta l_{\text{fin}})^2} \approx 0.22 \text{ m/sec}.$$

In the computations take care of the dimensions (as Δl is in centimetres, $g = 980 \text{ cm/sec}^2$).

Problem 107. An elastic beam supporting a weight at the centre of its span (Fig. 262) deflects by an amount δ_{st} (the static deflection of the beam). Neglecting the weight of the beam, determine its maximum deflection δ_{max} if the weight is dropped on it from a height H .

Fig. 262.

Solution. As in the previous problem, we apply Eq. (42). The initial velocity v_0 and the final velocity v_1 (at the instant of the maximum deflection of the beam)

of the weight are each zero, and Eq. (42) takes the form

$$\sum A_k = 0. \quad (a)$$

The forces doing work are the gravitational force P in the displacement M_0M_1 and the elastic force F of the beam in the displacement $M'M_1$. Also, $A(P) = P(H + \delta_{\text{max}})$, $A(F) = \frac{c}{2} \delta_{\text{max}}^2$, as for the beam $\Delta l_{\text{in}} = 0$, $\Delta l_{\text{fin}} = \delta_{\text{max}}$. Substituting these expressions into equation (a), we obtain

$$P(H + \delta_{\text{max}}) - \frac{c}{2} \delta_{\text{max}}^2 = 0.$$

But when the weight on the beam is in equilibrium the gravitational force is balanced by the elastic force. Consequently, $P = c\delta_{\text{st}}$, and the last equation can be written in the form

$$\delta_{\text{max}}^2 - 2\delta_{\text{st}} \delta_{\text{max}} - 2\delta_{\text{st}} H = 0.$$

Solving this quadratic equation, and taking into account that according to the conditions of the problem $\delta_{\text{max}} > 0$, we find

$$\delta_{\text{max}} = \delta_{\text{st}} + \sqrt{\delta_{\text{st}}^2 + 2H\delta_{\text{st}}}.$$

It is interesting to note that at $H = 0$ we have $\delta_{\text{max}} = 2\delta_{\text{st}}$. Thus, if the weight is placed at the centre of a horizontal beam the maximum deflection in the downward motion of the weight will be double the static deflection. The beam will vibrate together with the weight about the position of equilibrium. Resisting forces will damp the vibrations till the system is balanced at the position when the deflection of the beam is equal to δ_{st} .

Problem 108. Determine the initial velocity that should be imparted to a body projected vertically up from the surface of the earth for it to reach a given altitude H . Assume the gravitational force to be changing inversely to the square of the distance from the centre of the earth and neglect the resistance of the air.

Solution. This problem is solved by applying the theorem of the change in kinetic energy, the body being considered as a particle. Place the origin of a coordinate system in the centre of the earth (the centre of attraction) and direct the x axis in the direction of the motion (Fig. 263). Draw the moving particle M in an arbitrary position and the force F applied to it. From the conditions of the problem,

$$F = \frac{km}{x^2},$$

where m is the mass of the particle and k is a scalar factor.

To determine k , note that when the particle is on the surface of the earth ($x = R_0$, where R_0 is the radius of the earth) the gravitational force is mg_0 , where g_0 is the acceleration of gravity at the surface of the earth. Hence,

$$mg_0 = \frac{km}{R_0^2} \quad \text{and} \quad k = R_0^2 g_0.$$

By the theorem of the change in kinetic energy,

$$\frac{mv_1^2}{2} - \frac{mv_0^2}{2} = A_{(M_0 M_1)}. \quad (a)$$

When the particle reaches its highest position, $v_1 = 0$. To compute the work we take Eq. (38'). In our case

$$F_x = -F = -\frac{mk}{x^2}, \quad F_y = F_z = 0,$$

whence

$$A_{(M_0 M_1)} = \int_{(M_0)}^{(M_1)} \left(-\frac{km}{x^2} \right) dx = -km \int_{R_0}^{R_0+H} \frac{dx}{x^2}.$$

Integrating, we find

$$A_{(M_0 M_1)} = km \left(\frac{1}{R_0 + H} - \frac{1}{R_0} \right) = -\frac{kmH}{R_0(R_0 + H)}.$$

Substituting these expressions of the work and of k in equation (a), we finally obtain

$$v_0 = \sqrt{\frac{2g_0 R_0 H}{R_0 + H}}.$$

Fig. 263.

Let us consider some special cases.

a) If H is very small as compared with R_0 , H/R_0 is very small. Dividing the numerator and denominator by R_0 , we obtain

$$v_0 = \sqrt{\frac{2g_0 H}{1 + \frac{H}{R_0}}} \approx \sqrt{2g_0 H}.$$

Thus, at small values of H we obtain Galileo's formula.

b) Let us find the initial velocity which will carry a projectile into infinity. Dividing the numerator and denominator by H , we obtain

$$v_0 = \sqrt{\frac{2g_0 R_0}{1 + \frac{R_0}{H}}}.$$

At $H = \infty$, and assuming the mean radius of the earth to be $R_0 \approx 6,370$ km we obtain

$$v_0 = \sqrt{2g_0 R_0} \approx 11.2 \text{ km/sec.}$$

Thus, a body projected from the surface of the earth with a velocity of 11.2 km/sec will escape the earth's gravitational field forever.

It can be calculated that at initial velocities lying approximately within the limits $8 \text{ km/sec} \leq v_0 \leq 11 \text{ km/sec}$ a body projected at a tangent to the earth's surface will not fall back and will become an artificial satellite. At initial velocities below 8 km/sec or when a body is not projected horizontally, it will describe an elliptical trajectory and fall back to earth. All these results refer to motion in vacuo (see Chapter 22).

116. Theorem of the Change in the Angular Momentum of a Particle (the Principle of Moments). Of the two principal dynamic characteristics introduced in § 109, only $m\mathbf{v}$ is a vector quantity. Often, in analysing the motion of a particle, it is necessary to consider the change not of the vector $m\mathbf{v}$ itself, but of its moment. The moment of the vector $m\mathbf{v}$ with respect to any centre O or axis z is denoted by the symbol $\mathbf{m}_O(m\mathbf{v})$ or $m_z(m\mathbf{v})$ and is called the *moment of momentum* or *angular momentum* with respect to that centre or axis. The moment of vector $m\mathbf{v}$ is calculated in the same way as the moment of a force. Vector $m\mathbf{v}$ is considered to be applied to the moving particle. In magnitude $|\mathbf{m}_O(m\mathbf{v})| = mvh$, where h is the perpendicular distance from O to the position line of the vector $m\mathbf{v}$ (see Fig. 264).

1. Principle of Moments About an Axis*. Consider a particle of mass m moving under the action of a force \mathbf{F} . Let us establish the dependence between the moments of the vectors $m\mathbf{v}$ and \mathbf{F} with respect to any fixed axis z . From the formulas of § 42,

$$m_z(\mathbf{F}) = xF_y - yF_x. \quad (43)$$

* This result can be obtained as a special case of item 2.

Similarly, for $m_z(m\mathbf{v})$, and taking m out of the parentheses, we have

$$m_z(m\mathbf{v}) = m(xv_y - yv_x) \quad (43')$$

Differentiating both sides of this equation with respect to time, we obtain

$$\frac{d}{dt}[m_z(m\mathbf{v})] = m\left(\frac{dx}{dt}v_y - \frac{dy}{dt}v_x\right) + \left(xm\frac{dv_y}{dt} - ym\frac{dv_x}{dt}\right).$$

The expression in the first parentheses of the right side of the equation is zero, as $\frac{dx}{dt} = v_x$ and $\frac{dy}{dt} = v_y$. From Eq. (43), the expression in the second pair of parentheses is equal to $m_z(\mathbf{F})$, since, from the fundamental law of dynamics,

$$m\frac{dv_y}{dt} = F_y, \quad m\frac{dv_x}{dt} = F_x.$$

Finally, we have

$$\frac{d}{dt}[m_z(m\mathbf{v})] = m_z(\mathbf{F}). \quad (44)$$

This equation states the principle of moments about an axis: *The derivative of the angular momentum of a particle about any axis with respect to time is equal to the moment of the acting force about the same axis.* An analogous theorem can be proved for moments about any centre O . Its mathematical expression is given below in Eq. (45').

2. Principle of Moments about a Centre. Let us find for a particle moving under the action of a force \mathbf{F} (Fig. 264) the relation between the moments of vectors $m\mathbf{v}$ and \mathbf{F} with respect to any fixed centre O . It was shown at the end of § 41 that $m_o(\mathbf{F}) = \mathbf{r} \times \mathbf{F}$. Similarly,

$$m_o(m\mathbf{v}) = \mathbf{r} \times m\mathbf{v}.$$

Vector $m_o(\mathbf{F})$ is normal to the plane through O and vector \mathbf{F} , while the vector $m_o(m\mathbf{v})$ is normal to the plane through the centre O and vector $m\mathbf{v}$. Differentiating the expression $m_o(m\mathbf{v})$ with respect to time, we obtain

$$\frac{d}{dt}(\mathbf{r} \times m\mathbf{v}) = \left(\frac{d\mathbf{r}}{dt} \times m\mathbf{v}\right) + \left(\mathbf{r} \times m\frac{d\mathbf{v}}{dt}\right) = (\mathbf{v} \times m\mathbf{v}) + (\mathbf{r} \times m\mathbf{w}).$$

Fig. 264.

But $\mathbf{v} \times m\mathbf{v} = 0$, as the vector product of two parallel vectors, and $m\mathbf{w} = \mathbf{F}$. Hence,

$$\frac{d}{dt}(\mathbf{r} \times m\mathbf{v}) = \mathbf{r} \times \mathbf{F}, \quad (45)$$

or

$$\frac{d}{dt}[m_o(m\mathbf{v})] = m_o(\mathbf{F}). \quad (45')$$

This is the principle of moments about a centre: *The derivative of the angular momentum of a particle about any fixed centre with respect to time is equal to the moment of the force acting on the particle about the same centre.* An analogous theorem

is true for the moments of vector $m\mathbf{v}$ and force \mathbf{F} with respect to any axis z , which is evident if we project both sides of Eq. (45') on that axis. This was proved directly in item 1. The mathematical statement of the theorem of moments about an axis is given in Eq. (44) above.

A comparison of Eqs. (45') and (32) shows that the moments of vectors $m\mathbf{v}$ and \mathbf{F} are linked by the same relationship as the vectors $m\mathbf{v}$ and \mathbf{F} themselves.

Fig. 265.

Problem 109. A bead M attached to a string BM (Fig. 265) receives an initial velocity \mathbf{v}_0 such that \mathbf{v}_0 is perpendicular to the plane ABM . The motion of the bead makes the string wind round a thin vertical rod. The initial distance of the bead from the rod is h_0 . Neglecting the diameter of

the rod, determine the velocity v_1 of the bead when its distance from the rod is h_1 .

Solution. Acting on the bead are the force of gravity \mathbf{P} and the reaction of the string \mathbf{T} . The moments of these forces about the axis z , which is coincident with the rod, are zero. Then, from Eq. (44), we have

$$\frac{d}{dt}[m_z(m\mathbf{v})] = 0,$$

whence $m_z(m\mathbf{v}) = mvh = \text{const.}$ As the mass m is constant, it follows that during the motion of the bead $v_0 h_0 = v_1 h_1$, whence

$$v_1 = \frac{h_0}{h_1} v_0.$$

The closer the bead approaches the rod, the greater is its velocity.

3. Motion Under the Action of a Central Force. A *central force* is one whose line of action always passes through a given centre O . An example of a central force is the force with which the planets are attracted by the sun.

Using Eq. (45'), let us investigate how a particle M will move under the action of a central force \mathbf{F} (Fig. 266). As in this case $\mathbf{m}_o(\mathbf{F}) = 0$, $\mathbf{m}_o(m\mathbf{v}) = \mathbf{r} \times m\mathbf{v} = \text{const.}$, i.e., the vector $\mathbf{m}_o(m\mathbf{v})$ is constant both in magnitude and direction. It follows from this that, firstly, vectors \mathbf{r} and \mathbf{v} must always be in the same plane (so that the direction of vector $\mathbf{r} \times m\mathbf{v}$ would remain constant); hence, the path of the particle is a plane curve. Furthermore, since in magnitude $|\mathbf{m}_o(m\mathbf{v})| = \text{const.}$, and the mass m is also constant, $m_o(\mathbf{v}) = vh = \text{const.}$

Thus, a particle subjected to the action of a central force moves in a plane curve; its velocity \mathbf{v} changes in such a way that the moment of vector \mathbf{v} about the centre O is constant ($vh = \text{const.}$).

This result has a graphic geometrical interpretation. As $vh = \frac{ds}{dt} \cdot h$ and $ds \cdot h = 2d\sigma$, where $d\sigma$ is the area of the triangular element OMb , then it follows that, if $vh = 2\frac{d\sigma}{dt} = \text{const.}$, $\frac{d\sigma}{dt} = \text{const.}$

The quantity $\frac{d\sigma}{dt}$ represents the rate of increase of the area swept out by the radius vector OM in the motion of the particle M and is called the *areal velocity*. In the present case this velocity is constant. Thus, *in motion under the action of a central force the radius vector of a particle sweeps out equal areas in equal intervals of time (the Law of Areas)*. This applies to planetary motion and is one of Kepler's laws.

If the ellipse in Fig. 266 is the orbit of a planet moving about the sun, which is in the focus O of the ellipse, then at point P , which is called the *perihelion*, the planet has maximum velocity, and at point A , called the *aphelion*, it has minimum velocity. This follows from the fact that the areas of the shaded sectors swept out in equal times must be equal. The relation between the velocities v_P and v_A can also be found by equating their moments: $v_P OP = v_A OA$.

Fig. 266.

Chapter 19

CONSTRAINED MOTION OF A PARTICLE
AND D'ALEMBERT'S PRINCIPLE

117. **Equations of Motion of a Particle Along a Given Fixed Curve.** We have seen that some problems of constrained motion can be solved with the help of the general theorems of dynamics. Let us consider another method of solving such problems which can be used for any acting forces and which makes it possible to find both the equation of motion of a particle and the reactions of its constraints.

Let particle M in Fig. 267 be moving along a given smooth curve under the action of the applied forces $F_1^a, F_2^a, \dots, F_n^a$, let O be the origin of a frame of reference lying on the curve, and let the motion of the particle be described by the arc-coordinate $s = OM$ (see § 68). If we replace the constraint by its reaction N , the fundamental law of dynamics will take the form (see § 102):

$$m\mathbf{w} = \sum F_k^a + N. \quad (46)$$

Let us draw through point M the tangent $M\tau$ (in the positive direction of s), the principal normal Mn (inward to the curve), and an axis Mb perpendicular to them,

which is called the *binormal*, and project both sides of Eq. (46) on these axes. As the curve is smooth, the reaction N is perpendicular to it, i.e., lies in the plane Mbn , and consequently, $N_\tau = 0$. Thus we have:

$$m\omega_\tau = \sum F_{k\tau}^a, \quad m\omega_n = \sum F_{kn}^a + N_n, \quad m\omega_b = \sum F_{kb}^a + N_b.$$

But $\omega_\tau = \frac{dv}{dt} = \frac{d^2s}{dt^2}$, $\omega_n = \frac{v^2}{\rho}$, and $\omega_b = 0$, as the acceleration vector \mathbf{w} lies in the osculating plane $M\tau n$. This gives us the following *differential equations of motion of a particle along a given curve*:

$$m \frac{dv}{dt} = \sum F_{k\tau}^a, \quad \text{or} \quad m \frac{d^2s}{dt^2} = \sum F_{k\tau}^a; \quad (47)$$

$$\frac{mv^2}{\rho} = \sum F_{kn}^a + N_n, \quad 0 = \sum F_{kb}^a + N_b. \quad (48)$$

These equations can be used to solve both the problems of constrained motion mentioned in § 102.

Fig. 267.

Eq. (47), which does not contain the unknown reaction N , is convenient for developing the equation of motion of a particle along a curve, i.e., the relation $s = s(t)$. Eqs. (48) are used to determine the reaction of the constraint (see § 118).

These equations can also be used if the curve is not smooth, in which case the frictional force should be added to the forces F_k .

Eqs. (47) and (48) also hold for the motion of a free particle, in which case we assume $N = 0$.

Problem 110. A heavy ring M sliding on a horizontal wire circle of radius $R = 0.3$ m receives an initial velocity $v_0 = 2$ m/sec tangent to the circle (Fig. 268). The coefficient of friction of the ring on the circle is $f = 0.3$. Determine the distance s , the ring will travel along the circle before it stops.

Solution. Placing the origin O of the frame of reference at the initial position of the ring, we draw the ring in an arbitrary position and the axes $M\tau$, Mn and Mb . Acting on the ring are the force of gravity P , the reaction N , and the frictional force F . Writing Eqs. (47) and (48), we obtain:

$$m \frac{dv}{dt} = -F, \quad \frac{mv^2}{R} = N_n, \quad N_b - P = 0.$$

In magnitude $F = fN = f \sqrt{N_b^2 + N_n^2}$ (it would be wrong to compute the friction as the arithmetical sum of forces fN_b and fN_n). Noting that $N_b = P = mg$, we find

$$F = fm \sqrt{g^2 + \frac{v^4}{R^2}}.$$

We see that the friction depends, through the reaction N , on the velocity of the ring. That is why this problem cannot be solved by applying the theorem of the change in kinetic energy.

In order to find immediately the dependence of s on v , note that $\frac{dv}{dt} = \frac{dv}{ds} \frac{ds}{dt} = \frac{dv}{ds} v$. Then, eliminating m , the equation of motion of the ring takes the form

$$v \frac{dv}{ds} = -\frac{f}{R} \sqrt{g^2 R^2 + v^4}.$$

Separating the variables, we obtain

$$\frac{d(v^2)}{\sqrt{g^2 R^2 + v^4}} = \frac{2f}{R} ds,$$

whence

$$\frac{2f}{R} s = -\ln(v^2 + \sqrt{g^2 R^2 + v^4}) + C_1.$$

Fig. 268.

From the initial data, at $s=0$, the velocity $v=v_0$. Hence, $C_1 = \ln(v_0^2 + \sqrt{g^2 R^2 + v_0^4})$ and finally

$$s = \frac{R}{2f} \ln \frac{v_0^2 + \sqrt{g^2 R^2 + v_0^4}}{v^2 + \sqrt{g^2 R^2 + v^4}}.$$

When the ring stops, $v=0$. Thus, assuming $g \approx 10 \text{ m/sec}^2$, the required path is

$$s_1 = \frac{R}{2f} \ln \frac{v_0^2 + \sqrt{v_0^4 + g^2 R^2}}{gR} \approx \frac{1}{2} \ln 3 \approx 0.55 \text{ m}.$$

118. Determination of the Reactions of Constraints. The reaction of the constraint when a particle moves along a given curve is found with the help of Eq. (48). The moving particle should be drawn in the position for which the reaction is to be determined. If the velocity v in Eq. (48) is not immediately known, it can in some cases be found from the theorem of the change in kinetic energy (§ 114).

From Eq. (48) it can be seen that in curvilinear motion the dynamic reaction N , unlike static reaction, depends not only on the applied active forces and the type of constraint but also on the velocity of motion.

Fig. 269.

Problem 111. A load of weight P attached to a string of length l is displaced through an angle α from the vertical to a position M_0 and released from rest (Fig. 269). Determine the tension in the thread when the load is in its lowest position M_1 .

Solution. Draw the load in the position for which the tension in the string has to be found, i.e., in position M_1 . Acting on the load is its weight P and the reaction of the thread T . Draw the inward normal $M_1 n$ and write Eq. (48), taking into account that in the present case $q=l$. We have:

$$\frac{mv_1^2}{l} = T - P \quad \text{or} \quad T = P + \frac{mv_1^2}{l},$$

where v_1 is the velocity of the load at position M_1 . To determine v_1 , we make use of Eq. (42'):

$$\frac{mv_1^2}{2} - \frac{mv_0^2}{2} = A_{(M_0 M_1)}^a. \quad (a)$$

On the section $M_0 M_1$ only force P does any work. Therefore, $A^a = Ph = Pl(1 - \cos \alpha)$.

As $v_0=0$, substituting the expression developed for the work into equation (a), we obtain $mv_1^2 = 2Pl(1 - \cos \alpha)$, and finally

$$T = P(3 - 2 \cos \alpha).$$

In the special case, when the initial angle of deflection is 90° , the tension in the string when it is in vertical position will be $3P$, i.e., treble the weight of the load.

The result shows that dynamic reactions can differ considerably from static reactions.

Problem 112. A grooved track makes two circular arcs AB and BD of radius R in a vertical plane; the tangent BE through their point of conjugation is horizontal (Fig. 270).

Neglecting friction, determine the height h from BE at which a heavy ball should be placed on the track so that it would shoot out of the track at point M_1 lying at the same distance h below BE .

Solution. The ball will leave the track at a point M_1 such that its pressure on the track (or the reaction N of the track) is zero. Consequently, our problem is reduced to the determination of N . Draw the ball at M_1 . Acting on it are the force of gravity P and the reaction of the track N . Writing Eq. (48) for the projections on the inward normal M_1n , we have

$$\frac{mv_1^2}{R} = P \cos \varphi - N.$$

Since at the point of departure $N = 0$, and taking into account that $R \cos \varphi = KC = R - h$, for determining h we obtain the equation

$$mv_1^2 = P(R - h). \quad (a)$$

The value of mv_1^2 can be found from the theorem of the change in kinetic energy. As $v_0 = 0$, Eq. (42') gives

$$\frac{mv_1^2}{2} = A_{(M_0, M_1)}^P.$$

The only force that does work is P , and $A(P) = P2h$. Consequently $mv_1^2 = 4Ph$. Substituting this expression of mv_1^2 into equation (a), we obtain $4h = R - h$, whence

$$h = 0.2R.$$

Problem 113. A load M is attached to a string of length l (Fig. 271). What is the least initial velocity v_0 perpendicular to the string that should be imparted to the load for it to describe a complete circle?

Solution. The load will describe a complete circle if nowhere along its path (except, possibly, point M') will the tension in the string become zero, i.e., if the string remains taut. If, on the other hand, at any point M_1 where $v_1 \neq 0$ the tension becomes zero, the string will no longer constrain the load, which will continue to move as a free body (along a parabola).

To solve the problem we must determine the tension T in the string at any point M defined by angle φ and then require that $T > 0$ for any angle $\varphi \neq 180^\circ$.

Fig. 270.

Fig. 271.

Acting on the load at point M are its weight P and the tension of the thread T . Writing Eq. (48) for the projections on the inward normal Mn , we obtain

$$\frac{mv^2}{l} = T - P \cos \varphi, \quad (a)$$

where v is the velocity of the load at point M . To determine v we apply the theorem of the change in kinetic energy:

$$\frac{mv^2}{2} - \frac{mv_0^2}{2} = A_{(M_0M)}^a.$$

In our case $A_{(M_0M)}^a = -Ph = -Pl(1 - \cos \varphi)$, and consequently

$$mv^2 = mv_0^2 - 2Pl(1 - \cos \varphi).$$

Substituting this expression of mv^2 into equation (a) and solving for T , we obtain

$$T = P \left(\frac{v_0^2}{gl} - 2 + 3 \cos \varphi \right).$$

The least value of T is at $\varphi = 180^\circ$:

$$T_{\min} = P \left(\frac{v_0^2}{gl} - 5 \right).$$

The condition for T never to become zero (except, possibly, at point M') is that $T_{\min} \geq 0$. Hence

$$\frac{v_0^2}{gl} \geq 5 \quad \text{or} \quad v_0 \geq \sqrt{5gl}.$$

Thus, the least initial velocity at which the load will describe a complete circle is given by the equation

$$v_{0 \min} = \sqrt{5gl}.$$

Let us assume that the load is attached not to a thread but to a rigid light (weightless) rod of length l . In this case (since, unlike a thread, a rod can work both in tension and in compression) the load will describe a complete circle if the velocity does not become zero anywhere (except, possibly, at point M'). Applying Eq. (42') for the displacement M_0M' and assuming $v = 0$

at point M' , we obtain $-\frac{mv_0^2}{2} = -mg \cdot 2l$. Hence

$$v_{0 \min} = \sqrt{4gl}.$$

119. D'Alembert's Principle. Consider a particle M moving along a given fixed curve or surface (Fig. 272). The resultant of all the active forces applied to the particle is denoted by the symbol F^a . If the action of the constraint is replaced by its reaction N , the particle can be considered as a free body moving under the action of forces F^a and N . Let us see what force F^i should be

added to the forces F^a and N to balance them. If the resultant of the forces F^a and N is R , then, obviously, the required force $F^i = -R$.

Let us express force F^i in terms of the acceleration of the moving particle. As, according to the fundamental law of dynamics, $R = m\omega$,

$$F^i = -m\omega.$$

The force F^i , equal in magnitude to the product of the mass of the particle and its acceleration and directed oppositely to the acceleration, is called the *inertia force* of the particle M .

Thus, if to the forces F^a and N is added the inertia force F^i , the forces will be balanced, and we will have

$$F^a + N + F^i = 0. \quad (49)$$

This equation states *D'Alembert's principle for a particle*: If at any given moment to the active forces and the reactions of the constraints acting on a particle is added the inertia force, the resultant force system will be in equilibrium and all the equations of statics will apply to it.

D'Alembert's principle provides a method of solving problems of dynamics by developing equations of motion in the form of equations of equilibrium. The value of this method will be especially appreciated in investigating the dynamics of a system.

In applying D'Alembert's principle it should always be remembered that actually *only* forces F^a and N are acting on a particle and that the particle is in motion. The inertia force *does not* act on a moving particle and the concept is introduced for the sole purpose of developing equations of dynamics with the help of the simpler methods of statics.

The force equal to $-m\omega$ is called the "inertia force" in mechanics for the following reason. If, for instance, your hand pushes a load in a straight line with an acceleration, it acts on the load with a force $F = m\omega$. From the law of action and reaction it follows that the load in turn acts on your hand with a force $Q = -m\omega$ resisting the change of velocity. As the force $Q = -m\omega$ is due to the inertia of the load, it can be called in this sense the "inertia force". This example only explains the meaning of the term "inertia force" for the quantity $-m\omega$. It will be noticed, however, that the force Q introduced here acts not on the load but on the hand accelerating the load. As was indicated, no inertia force actually acts on the load itself.

In order to denote inertia force in problem solutions we must know the direction of acceleration of the given particle. When

Fig. 272.

the motion is rectilinear the direction of \mathbf{w} is known, and \mathbf{F}^i is of opposite sense and in magnitude is $F^i = m\omega$.

In curvilinear motion the inertia force can be expressed by its tangential and normal components. Projecting both sides of the equation $\mathbf{F}^i = -m\mathbf{w}$ on the tangent and principal normal to the trajectory, we obtain

$$F_t^i = -m\omega_t = -m \frac{dv}{dt}, \quad F_n^i = -m\omega_n = -\frac{mv^2}{\rho}.$$

These equations show that the *tangential inertia force* F_t^i is directed opposite to the tangential acceleration (i.e., in the direction of the velocity decreasing), and the *normal, or centrifugal, inertia force* F_n^i is directed along the principal normal to the path away from the centre of curvature (as the vector \mathbf{w}_n is always directed towards the centre of curvature). In magnitude

$$|F_t^i| = m \left| \frac{dv}{dt} \right|, \quad |F_n^i| = \frac{mv^2}{\rho}.$$

D'Alembert's principle can be used to determine the dynamic reactions of constraints or the acceleration of a moving particle. In particular, the method is convenient for solving problems of the type discussed in §§ 103 and 118.

Problem 114. When a train accelerates, a load attached to a string hanging from the ceiling of a carriage deflects by an angle α from the vertical (Fig. 273). Determine the acceleration of the carriage.

Fig. 273.

Fig. 274.

Solution. Acting on the load is the force of gravity P and the reaction of the thread T . Applying D'Alembert's principle, add to these forces the inertia force F^i directed opposite to the acceleration \mathbf{w} of the carriage. In magnitude $F^i = m\omega = \frac{P}{g} \omega$. The forces P , T , and F^i are balanced. Constructing a closed force triangle, we find that

$$F^i = P \tan \alpha \text{ or } \frac{P}{g} \omega = P \tan \alpha.$$

Hence, the acceleration of the carriage is $\omega = g \tan \alpha$.

Problem 115. Solve Problem III by applying D'Alembert's principle.

Solution. Draw the load in the position for which the tension in the thread is required (Fig. 274). The forces acting on the load are the gravitational force P and the reaction of the thread T . Add to these the normal and tangential inertia forces F_n^i and F_t^i . By D'Alembert's principle the resultant force system is in equilibrium. Equating the sum of the projections of all the forces on the normal M_1O to zero, we obtain $T - P - F_n^i = 0$. As $F_n^i = \frac{mv_1^2}{l}$, where v_1 is the velocity of the load in position M_1 ,

$$T = P + F_n^i = P + \frac{mv_1^2}{l}.$$

Thus we obtain for T the same expression as in Problem III. Now determine the value of v_1 by applying the theorem of the change in kinetic energy, as in Problem III, and the required result is obtained.

The equation in terms of the projections on the tangent gives $F_t^i = 0$. This result is obtained because at point M_1 the derivative $\frac{dv}{dt} = 0$, as at that point the velocity is maximum.

Chapter 20

RELATIVE MOTION OF A PARTICLE

120. Equations of Relative Motion and Rest of a Particle. The laws of dynamics and the equations and theorems based on them which were obtained in the previous chapters are valid only for so-called absolute motion of a particle, i.e., motion with respect to an inertial (fixed) reference system.

The present chapter deals with relative motion of a particle, i.e., motion with respect to non-inertial, arbitrarily moving reference systems.

Consider a particle M moving under the action of applied forces F_1, F_2, \dots, F_n resulting from its interaction with other material bodies. Let us investigate the motion of this particle with respect to a set of coordinate axes $Oxyz$ (Fig. 275) which are in turn moving in some known way with respect to a set of fixed axes $O_1x_1y_1z_1$.

Let us find the relation between the relative acceleration of the particle w_{rel} and the forces acting on it. For absolute motion the fundamental law of dynamics has the form

$$mw_a = \sum F_k. \quad (50)$$

Fig. 275.

But we know from kinematics that $\mathbf{w}_a = \mathbf{w}_{\text{rel}} + \mathbf{w}_{\text{tr}} + \mathbf{w}_{\text{cor}}$, where \mathbf{w}_{rel} , \mathbf{w}_{tr} , and \mathbf{w}_{cor} are the relative, transport and Coriolis accelerations of the particle. Substituting this expression of \mathbf{w}_a into Eq. (50) and assuming for the future that $\mathbf{w}_{\text{rel}} = \mathbf{w}$, as this is the acceleration of the relative motion under consideration, we obtain

$$m\mathbf{w} = \sum \mathbf{F}_k + (-m\mathbf{w}_{\text{tr}}) + (-m\mathbf{w}_{\text{cor}}).$$

Let us introduce the following notation:

$$\mathbf{F}_{\text{tr}}^i = -m\mathbf{w}_{\text{tr}}, \quad \mathbf{F}_{\text{cor}}^i = -m\mathbf{w}_{\text{cor}}.$$

In dimension the quantities \mathbf{F}_{tr}^i and $\mathbf{F}_{\text{cor}}^i$ are forces, which we shall call respectively the *transport* and *Coriolis inertia forces*. Then the foregoing equation will take the form

$$m\mathbf{w} = \sum \mathbf{F}_k + \mathbf{F}_{\text{tr}}^i + \mathbf{F}_{\text{cor}}^i. \quad (51)$$

Eq. (51) states the *Fundamental Law of Dynamics for the relative motion of a particle*. A comparison of Eqs. (50) and (51) leads us to the conclusion: *All equations and theorems of mechanics for relative motion of a particle can be written exactly like the equations of absolute motion, provided that the transport and Coriolis inertia forces are added to the forces of interaction with other bodies acting on the particle*. The addition of forces \mathbf{F}_{tr}^i and $\mathbf{F}_{\text{cor}}^i$ takes into account the effect of the displacement of the moving axes on the relative motion of the particle.

Let us consider several special cases.

1. If the moving axes are in translatory motion, $\mathbf{F}_{\text{cor}}^i = 0$, as $\mathbf{w}_{\text{tr}} = 0$, and the equation of relative motion acquires the form

$$m\mathbf{w} = \sum \mathbf{F}_k + \mathbf{F}_{\text{tr}}^i.$$

2. If the moving axes are in uniform rectilinear translatory motion, $\mathbf{F}_{\text{tr}}^i = \mathbf{F}_{\text{cor}}^i = 0$, and the equation of relative motion is in the same form as the equation of motion relative to fixed axes. Therefore, such a reference system is also *inertial*.

It follows from this that it is impossible to determine by mechanical experiment whether a given reference system is at rest or in uniform rectilinear translatory motion. This is the *basic principle of relativity of classical mechanics* discovered by Galileo.

3. If a particle is at rest with respect to a moving set of axes, $\mathbf{w} = 0$ and $\mathbf{v}_{\text{rel}} = \mathbf{v} = 0$, and consequently $\mathbf{F}_{\text{cor}}^i = 0$, since the

Coriolis acceleration $\omega_{\text{cor}} = 2\omega_{\text{tr}}v_{\text{rel}} \sin \alpha$, and Eq. (51) takes the form

$$\sum F_k + F_{\text{tr}}^i = 0. \quad (52)$$

Eq. (52) is the *equation of relative equilibrium (rest) of a particle*. It follows from it that *equations of relative equilibrium can be written like the equations of equilibrium in fixed axes, provided that the transport inertia force is added to the forces of interaction with other bodies acting on the particle*.

4. In developing the equations of relative motion for cases when $F_{\text{cor}}^i \neq 0$, it should be remembered that

$$F_{\text{cor}}^i = -m\omega_{\text{cor}} = -2m(\omega_{\text{tr}} \times v_{\text{rel}}).$$

Consequently, F_{cor}^i is *perpendicular* to $v_{\text{rel}} = v$, and hence to the tangent to the relative path of the particle

Therefore:

a) the projection of the Coriolis inertia force on the tangent $M\tau$ to the relative path of a particle is always zero ($F_{\text{cor}}^i \tau = 0$) and Eq. (47) for relative motion (assuming $v = v_{\text{rel}}$) takes the form

$$m \frac{dv}{dt} = \sum F_k + F_{\text{tr}}^i; \quad (53)$$

b) the work done by the Coriolis inertia force in any relative displacement is zero (see § 112, Eq. (38)), and in relative motion *the theorem of the change in kinetic energy takes the form* (v_1 and v_0 denoting the *relative* velocities):

$$\frac{mv_1^2}{2} - \frac{mv_0^2}{2} = \sum A_k + A(F_{\text{tr}}^i). \quad (54)$$

In the general case both the transport and Coriolis inertia forces will enter into all the other equations of relative motion.

Problem 116. Neglecting the mass of all the rotating parts of the centrifugal-type governor in Fig. 276 as compared with the mass of the balls B and D , determine the angle α defining the position of relative equilibrium of rod AB of length l if the governor rotates with a constant angular velocity ω .

Solution. In order to determine the position of relative equilibrium (with respect to a set of axes rotating together with the governor) add, according to Eq. (52), to the force of gravity P and the reaction N acting on ball B the transport inertia force F_{tr}^i . As $\omega = \text{const.}$, $\omega_{\text{tr}} = \omega_{\text{tr}}^n = BC \cdot \omega^2 =$

Fig. 276.

$=l\omega^2 \sin \alpha$, whence $F_{tr}^i = ml\omega^2 \sin \alpha$. Writing the equilibrium equation for the projections on axis $B\tau$, which is perpendicular to AB , we have

$$-P \sin \alpha + F_{tr}^i \cos \alpha = 0.$$

Hence, substituting for F_{tr}^i its expression and eliminating $\sin \alpha$ (not considering the solution for $\alpha = 0$), we obtain

$$-g + l\omega^2 \cos \alpha = 0,$$

whence

$$\cos \alpha = \frac{g}{l\omega^2}.$$

As $\cos \alpha \leq 1$, equilibrium at $\alpha \neq 0$ is possible only when $\omega^2 > \frac{g}{l}$.

Problem 117. The semicircle BCD of radius R in Fig. 277 rotates about a vertical axis with a constant angular velocity ω . A ring M starts slipping along it without friction from a point B slightly off the axis of rotation. Determine the relative velocity v_1 of the ring at point C if its initial velocity $v_0 = 0$.

Fig. 277.

Solution. The velocity v_1 can be determined from the theorem of the change in kinetic energy. In order to write Eq. (54), which expresses the theorem, compute the work done by forces P and F_{tr}^i , where $F_{tr}^i = m\omega^2 x$ (the work done by the reaction N is zero). Assuming approximately $x_B = 0$, we obtain

$$A_{(BC)}(F_{tr}^i) = \int_{(B)}^{(C)} F_{tr}^i x dx = m\omega^2 \int_0^R x dx = \frac{1}{2} m\omega^2 R^2.$$

Furthermore, $A_{(BC)}(P) = PR$. Substituting these expressions into Eq. (54) and taking into account that $v_0 = 0$, we have

$$\frac{mv_1^2}{2} = mR \left(g + \frac{1}{2} \omega^2 R \right),$$

whence

$$v_1 = \sqrt{2gR \left(1 + \frac{\omega^2 R}{2g} \right)}.$$

The problem can also be solved by writing Eq. (53) for the projection on the tangent $M\tau$ and then transforming its left side as in Problem 110.

An example of the integration of equations of relative motion is given in § 123.

121. Effect of the Rotation of the Earth on the Equilibrium and Motion of Bodies. In solving most engineering problems we consider any reference system connected with the earth as fixed (inertial). We thereby neglect the diurnal rotation of the earth and its orbital motion about the sun. Since ordinarily the time

in problems is much less than a year, the motion of the earth along its orbit in the corresponding intervals can, for all practical purposes, be assumed to be uniform and rectilinear. It follows then that in considering a reference system connected with the earth as inertial, we primarily neglect its diurnal rotation together with the earth relative to the stars. The velocity of this rotation is one revolution in 23 hours 56 minutes 4 seconds, i.e., its angular velocity is

$$\omega = \frac{2\pi}{86,164} \approx 0.0000729 \text{ sec}^{-1}.$$

Let us investigate the effect of this rather slow rotation on the equilibrium and motion of bodies.

1. Relative Rest on the Surface of the Earth. Gravity. Consider a particle lying on a smooth "horizontal" plane which is motionless relative to the earth (Fig. 278). From Eq. (52), the condition of its equilibrium with respect to the earth is $\mathbf{F}_{gr} + \mathbf{N} + \mathbf{F}_{tr}^i = 0$, where \mathbf{F}_{gr} is the force of the earth's gravitational attraction, \mathbf{N} is the reaction of the surface, and \mathbf{F}_{tr}^i is the transport inertia force. As $\omega = \text{const.}$, force \mathbf{F}_{tr}^i has only a normal component, which is perpendicular to the earth's axis of rotation. Let us compound forces \mathbf{F}_{gr} and \mathbf{F}_{tr}^i and introduce the notation

$$\mathbf{F}_{gr} + \mathbf{F}_{tr}^i = \mathbf{P}.$$

Acting now on the particle M are two forces \mathbf{P} and \mathbf{N} , which balance one another. Force \mathbf{P} is the relative gravitational force of attraction exerted on, or the *weight* of, the particle M . The direction of force \mathbf{P} gives the vertical in any given point of the earth's surface, and the plane normal to \mathbf{P} is the horizontal plane. In magnitude $F_{tr}^i = mr\omega^2$ (where r is the distance of M from the earth's axis) and is very small in comparison with F_{gr} , since the value of ω^2 is very small. Therefore, the direction of \mathbf{P} will differ only slightly from the direction of \mathbf{F}_{gr} *.

Fig. 278.

* The value of F_{tr}^i is largest at the equator, where $r = R$ and where it is approximately 0.34 per cent of the absolute gravitational attraction. The greatest difference between the angles λ (the geocentric latitude) and φ (the astronomical latitude) in Fig. 278 is at $\lambda = 45^\circ$ and is approximately equal to $11'$.

When we weigh a body we determine the force P , which is the force with which the body presses on the tray of a balance. Thus, by introducing force P into our equations, we introduce the force F_{tr}^i as well, i.e., we actually take into account the rotation of the earth.

2. *Relative Motion Near the Surface of the Earth.* To take into account the rotation of a system of axes connected with the earth, we must add to the applied forces acting on a particle the forces F_{tr}^i and F_{cor}^i . But force F_{tr}^i is included in force P and is taken into account by the introduction of the latter into the equations of motion. Consequently, *when we consider a set of axes connected with the earth to be fixed, we actually neglect only the Coriolis inertia force*

$$F_{cor}^i = 2m\omega v \sin \alpha,$$

where ω is the angular velocity of the earth and α is the angle between the relative velocity v of the particle and the earth's axis.

As ω is very small, then, if the velocity v is not very large, the force F_{cor}^i can be neglected in comparison with the force of gravity. For example, even at $v = 700$ m/sec (the velocity of a gun shell) and $\alpha = 90^\circ$, F_{cor}^i is only one per cent of P . Therefore in most engineering problems involving the motion of bodies coordinate systems connected with the earth can safely be treated as inertial (fixed).

The rotation of the earth becomes a factor of practical importance either at very large velocities (the flight of long-range missiles) or for motions of very long duration (river, atmospheric, and ocean currents).

Let us investigate the qualitative effect the earth's rotation has on the motion of bodies.

a) *Motion on the Surface of the Earth.* When a body moves down a meridian from north to south in the Northern Hemisphere, the Coriolis acceleration w_{cor} is directed eastwards (§ 93, Problem 88) and the force F_{cor}^i westwards. If the motion is reversed, force F_{cor}^i will, evidently, be eastwardly. In both cases, we find, the force will tend to displace a particle *to the right* with respect to the direction of motion.

If a particle moves eastwards along a parallel, the acceleration w_{cor} will be directed along the radius MC of that parallel (Fig. 279), force F_{cor}^i pointing in the opposite direction. The vertical component of this force (along OM) will change the weight of the body somewhat, while the horizontal component will point southward,

thus also deflecting the particle to the right of the direction of motion. The result is analogous if we take the motion westwardly along a parallel.

We conclude, then, that in the Northern Hemisphere a body moving along the earth's surface in any direction is deflected by the rotation of the earth to the right of the direction of its motion. In the Southern Hemisphere the deflection is to the left.

It is this that explains why in the Northern Hemisphere rivers undermine their right banks (Baer's Law). This, too, is what deflects steady winds (the Trade Winds) and ocean currents.

b) Vertical Fall. In order to determine the direction of the Coriolis inertia force F_{cor}^i acting on a freely falling particle, we must know the direction of its relative velocity \mathbf{v} .

As F_{cor}^i is very small as compared with the force of gravity, the vector \mathbf{v} can be considered in the first approximation to be directed vertically down, i.e., along MO in Fig. 279.

In this case, apparently, the vector $\boldsymbol{\omega}_{\text{cor}}$ will point westwards, and the

force F_{cor}^i eastwards (i.e., in the direction of vector \mathbf{v} in Fig. 279). Thus, in the first approximation, a freely falling particle (body) is deflected by the earth's rotation to the east of the vertical. A body thrown vertically up will, evidently, be deflected towards the west. These deflections are very small and are noticeable only if the height is large enough, as is demonstrated by the calculations in § 122.

Fig. 279.

122. Deflection of a Falling Particle from the Vertical by the Earth's Rotation. Consider a particle falling from a small height H (as compared with the radius of the earth) to the surface of the earth. We shall assume that the gravitational force \mathbf{P} is constant and neglect the resistance of the air. Direct axis Oy vertically up and axis Ox to the east (Fig. 280a)*. To take into account the rotation of the earth, we must add to the forces acting on the particle, besides force \mathbf{P} which already includes force F_{tr}^i , the force F_{cor}^i , which in the first approximation is directed, as has been established, to the east. Then the differential equations of relative motion will take the form

$$m \frac{d^2 x}{dt^2} = F_{\text{cor}}^i, \quad m \frac{d^2 y}{dt^2} = -P = -mg, \quad (55)$$

* The scale in the direction of the x axis in Fig. 280 is considerably magnified.

and the initial conditions will be

$$\text{at } t=0, \quad x=0, \quad y=H; \quad v_x=0, \quad v_y=0.$$

Integrating the second of Eqs. (55) and determining the constants of integration from the initial conditions, we find

$$v_y = \frac{dy}{dt} = -gt, \quad y = H - \frac{gt^2}{2}.$$

In calculating the magnitude of F_{cor}^i we neglect, as we did previously in determining the direction of F_{cor}^i , the x component of the velocity as compared with the y component (as F_{cor}^i is much less than P), and for our approx-

Fig. 280.

imate solution we assume $v = |v_y| = gt$. The velocity v is in this case, directed vertically down (along MO in Fig. 279) and makes an angle $\alpha = 90^\circ - \lambda$ with the earth's axis of rotation, where λ is the latitude. Hence, $F_{\text{cor}}^i = 2m\omega gt \cos \lambda$, and the first of the Eqs. (55) takes the form

$$\frac{d^2x}{dt^2} = 2(\omega g \cos \lambda) t.$$

As the quantity inside the parentheses is constant, integrating the equation, we obtain

$$\frac{dx}{dt} = (\omega g \cos \lambda) t^2 + C_1, \quad x = \frac{1}{3} (\omega g \cos \lambda) t^3 + C_1 t + C_2.$$

Substituting the initial data, we find that $C_1 = C_2 = 0$. Thus, the equations approximately describing the relative motion of the particle are:

$$x = \frac{1}{3} (\omega g \cos \lambda) t^3, \quad y = H - \frac{gt^2}{2}.$$

The motion is not rectilinear, and the falling particle is actually deflected to the east. Eliminating time t from the last two equations, we obtain the path of the particle in the first approximation (a semicubical parabola):

$$x^2 = \frac{8}{9} \frac{\omega^2}{g} \cos^2 \lambda (H - y)^3.$$

Assuming $y = 0$, we obtain the eastward deflection ε of the particle when it reaches the earth*:

$$\varepsilon = \frac{2}{3} \omega \cos \lambda \sqrt{\frac{2H^3}{g}}. \quad (56)$$

We see that the deflection ε is proportional to the earth's angular velocity ω and, consequently, is a very small quantity. On the latitude of Moscow, for example ($\lambda = 55^\circ 47'$, $g = 9.816 \text{ m/sec}^2$), for a fall from a height of 100 m, $\varepsilon = 1.2 \text{ cm}$.

Experiments carried out in many parts of the globe by different researchers confirm the validity of Eq. (56).

Consider now the motion of a particle thrown from a point O vertically up with an initial velocity v_0 . In the first approximation the force F_{cor}^i in the ascent is directed westward. Then, if we direct the x axis to the west (Fig. 280b), the differential equation of motion will be of the form (55) and the initial conditions will be: at $t = 0$, $x = y = 0$, $v_x = 0$, $v_y = v_0$.

Thus the second of the Eqs. (55) will give

$$v_y = v_0 - gt; \quad y = v_0 t - \frac{gt^2}{2}. \quad (57)$$

Then, assuming approximately, as in the previous problem, that $v = v_y$, we obtain $F_{\text{cor}}^i = 2m\omega(v_0 - gt)\cos\lambda$, and the first of the Eqs. (55) takes the form

$$\frac{d^2x}{dt^2} = 2(\omega \cos \lambda)(v_0 - gt).$$

This equation describes the motion of a particle in its downward fall as well, since the change in the sense of the vector F_{cor}^i is taken into account by the change in the sign of the multiplier $(v_0 - gt) = v_y$.

Integrating the obtained equation for the initial conditions of the problem, we find finally

$$x = \omega \cos \lambda \left(v_0 t^2 - \frac{1}{3} g t^3 \right). \quad (58)$$

Assuming in Eq. (57) $y = 0$, we can determine the time it takes the particle to reach the ground: $t_1 = 2 \frac{v_0}{g}$. Taking into account at the same time that $v_0 = \sqrt{2gH_1}$, where H_1 is the height of the ascent, we can determine from Eq. (58) the westward deflection of the particle at the moment it touches the ground:

$$OB = \varepsilon_1 = \frac{4}{3} \omega \cos \lambda \frac{v_0^3}{g^2} = \frac{8}{3} \omega \cos \lambda \sqrt{\frac{2H_1^3}{g}}. \quad (59)$$

* In determining the magnitude and direction of F_{cor}^i , in the first approximation we neglected the x component of the velocity, which is eastwardly directed. Due to this velocity, F_{cor}^i has an additional component which deflects the particle to the south. As $x = \frac{1}{3}(\omega g \cos \lambda) t^3$, the quantity $v_x = \frac{dx}{dt}$ is proportional to ω , and the southward deflection is proportional to ω^2 , i.e., it is a small quantity of the second order.

Eqs. (56) and (59) show that at $H_1 = H$ the deflection $\varepsilon_1 = 4e$.

If the particle can continue moving (the point of projection O is not on the ground), the path of the particle from point B will deflect continuously to the east.

All these calculations, as has been pointed out, refer to motion in vacuo and take the earth's rotation into account only in the first approximation.

Chapter 21

VIBRATION OF A PARTICLE

123. Free Harmonic Motion. The study of vibrations is essential for a number of physical and engineering fields. Although the vibrations studied in such different fields as mechanics, radio engineering, and acoustics are of different physical nature, the fundamental laws hold good for all of them. The study of mechanical vibrations is therefore of importance not only because they are frequently encountered in engineering but also because the results obtained in investigating mechanical vibrations can be used in studying and understanding vibration phenomena in other fields.

Fig. 281.

We shall start with examining free harmonic motion of a particle. Consider a particle M (Fig. 281) moving rectilinearly under the action of a *restoring force* F directed towards a fixed centre O and proportional to the distance from that centre. The projection of F on the axis Ox is

$$F_x = -cx. \quad (60)$$

We see that the force F tends to return the particle to its position of equilibrium O , where $F=0$, which is why it is called a "restoring" force. Examples of such a force are an elastic force (§ 113, Fig. 255) and the force of attraction analysed in Problem 99 (p. 238).

Let us derive the equation of motion of the particle M . Writing the differential equation of motion (6), we obtain

$$m \frac{d^2x}{dt^2} = -cx.$$

Dividing both sides of the equation by m and introducing the notation

$$\frac{c}{m} = k^2, \quad (61)$$

For example, from position M at phase φ the particle will move to the right, at phase $(\pi - \varphi)$ it will move to the left. Phases differing by 2π are considered identical (the little circles in Fig. 138c indicate identical phases). The quantity α defines the *initial phase*, with which the motion begins. For example, at $\alpha = 0$ the motion is according to the sine law (it begins at O and the velocity is directed to the right); and at $\alpha = \frac{\pi}{2}$ the motion is according to the cosine law (starting from point $x = a$ with a velocity $v_0 = 0$). The quantity k which coincides with the angular velocity of the rotating radius OB in Fig. 282 is called the *angular, or circular, frequency of vibration*.

The time T (or τ) in which the moving particle makes one complete oscillation is called the *period of vibration*. In one period the phase changes by 2π . Consequently, we must have $kT = 2\pi$, whence the period

$$T = \frac{2\pi}{k}. \quad (66)$$

The quantity ν , which is the inverse of the period and specifies the number of oscillations per second is called the *frequency of vibration*:

$$\nu = \frac{1}{T} = \frac{k}{2\pi}. \quad (67)$$

It can be seen from this that the quantity k differs from ν only by a constant multiplier 2π . Usually we shall speak of the quantity k as of frequency.

The values of a and α are determined from the initial conditions. Assuming that, at $t = 0$, $x = x_0$ and $v_x = v_0$, we obtain from Eqs. (64) and (65) $x_0 = a \sin \alpha$ and $\frac{v_0}{k} = a \cos \alpha$. By first squaring and adding these equations and then dividing them, we obtain

$$a = \sqrt{x_0^2 + \frac{v_0^2}{k^2}}, \quad \tan \alpha = \frac{kx_0}{v_0}. \quad (68)$$

Note the following properties of free harmonic motion:

- 1) the amplitude and initial phase *depend* on the initial conditions;
- 2) the frequency k , and consequently the period T , *do not depend* on the initial conditions [see Eqs. (61) and (66)] and are invariable characteristics for a given vibrating system.

It follows, in particular, that if a problem requires that only the period (or frequency) of vibration be determined, it is necessary to write a differential equation of motion in the form (62). Then T is found immediately from Eq. (66) without integrating.

Problem 118. A weight is attached to end B of a vertical spring AB and released from rest. Determine the law of motion of the weight if the elongation of the spring in the equilibrium condition is δ_{st} (the static elongation of the spring).

Solution. Place the origin O of the coordinate axis in the position of static equilibrium of the system and direct the axis Ox vertically down (Fig. 283). The elastic force $F = c|\Delta l|$. In our case $\Delta l = \delta_{st} + x$, hence

$$F_x = -c(\delta_{st} + x).$$

Writing the differential equation of motion, we obtain

$$m \frac{d^2 x}{dt^2} = -c(\delta_{st} + x) + P.$$

But from the conditions of the problem the gravitational force $P = mg = c\delta_{st}$ (in the position of equilibrium force P is balanced by the elastic force $c\delta_{st}$).

Introducing the notation $\frac{c}{m} = \frac{g}{\delta_{st}} = k^2$, we reduce the equation to the form

$$\frac{d^2 x}{dt^2} + k^2 x = 0,$$

whence immediately we find the period of vibration:

$$T = \frac{2\pi}{k} = 2\pi \sqrt{\frac{\delta_{st}}{g}}. \quad (a)$$

Thus, the period of vibration is proportional to the square root of the static elongation of the spring (this holds good also for a load vibrating on an elastic beam, where δ_{st} is the static deflection of the beam).

The solution of the obtained differential equation is

$$x = C_1 \sin kt + C_2 \cos kt.$$

From the initial conditions, at $t=0$, $x = -\delta_{st}$, and $v_x = 0$. As

$$v_x = \frac{dx}{dt} = kC_1 \cos kt - kC_2 \sin kt,$$

substituting the initial conditions, we obtain $C_2 = -\delta_{st}$, $C_1 = 0$. Hence, the amplitude of vibration is δ_{st} and the motion is according to the law

$$x = -\delta_{st} \cos kt.$$

We see that the maximum elongation of the spring in this motion is $2\delta_{st}$. The same result was obtained in a different way in Problem 107, where a beam played the role of the spring.

This solution shows that a constant force P does not change the type of motion under the action of an elastic force F but only shifts the centre of the vibrations in the direction of the action of the force by the quantity δ_{st} (without the force P the vibration would, evidently, be about B).

Problem 119. Determine the periods of vibration of a load of weight P attached to two springs of stiffness c_1 and c_2 as shown in Figs 284a and b.

Solution. a) In the first case, in the static position both springs are subjected to a tensile force P . Therefore, the static elongations are $\delta_{1st} = \frac{P}{c_1}$,

Fig. 283.

$\delta_{2st} = \frac{P}{c_2}$, and the total elongation is

$$\delta_{st} = \delta_{1st} + \delta_{2st} = \frac{P(c_1 + c_2)}{c_1 c_2},$$

and

$$c_{eq} = \frac{c_1 c_2}{c_1 + c_2},$$

where c_{eq} is the equivalent spring constant of the two given springs. In particular, at $c_1 = c_2$ we have $c_{eq} = \frac{1}{2}c$.

From formula (a) of Problem 118 the period of vibration is

$$T = 2\pi \sqrt{\frac{\delta_{st}}{g}} = 2\pi \sqrt{\frac{P(c_1 + c_2)}{g c_1 c_2}}.$$

Fig. 284.

b) In the second case the top spring is subjected to a tensile force P_1 , and the bottom spring is subjected to a compressive force P_2 , such that $P_1 + P_2 = P$. For these springs

we have $\delta_{1st} = \frac{P_1}{c_1}$, $\delta_{2st} = \frac{P_2}{c_2}$. But obviously $\delta_{1st} = \delta_{2st} = \delta_{st}$, and by virtue of the property of proportions

$$\delta_{st} = \frac{P_1}{c_1} = \frac{P_2}{c_2} = \frac{P_1 + P_2}{c_1 + c_2} \text{ or } \delta_{st} = \frac{P}{c_1 + c_2}.$$

The equivalent stiffness $c_{eq} = c_1 + c_2$ and the period of vibration

$$T = 2\pi \sqrt{\frac{\delta_{st}}{g}} = \sqrt{\frac{P}{g(c_1 + c_2)}}.$$

124. The Simple Pendulum. A simple pendulum consists of a small body attached to an inextensible string of negligible weight which oscillates in a vertical plane. We also neglect the size of the body as compared with the length l of the string and regard it as a particle. This particle is constrained to move on a circular arc of radius l . Choosing the origin O of a frame of reference and the positive direction of the arc $s = \widehat{OM}$ (or the angle φ) (Fig. 285), draw the bob in an arbitrary position M and the axis $M\tau$ in the positive direction of s .

Fig. 285.

Writing the differential equation of motion (47) (see § 117), we obtain

$$m \frac{d^2 s}{dt^2} = -P \sin \varphi.$$

Let us replace the coordinate s by the angle φ . We have $s = l\varphi$, and, eliminating m ,

$$\frac{d^2 \varphi}{dt^2} + \frac{g}{l} \sin \varphi = 0. \quad (69)$$

This differential equation cannot be integrated in ordinary functions. Let us consider only the case of *small oscillations* of the pendulum, assuming approximately $\sin \varphi \approx \varphi$ (this is possible when angle φ is much less than a radian). Then, denoting $\frac{g}{l} = k^2$, Eq. (69) takes the form

$$\frac{d^2\varphi}{dt^2} + k^2\varphi = 0. \quad (70)$$

We conclude that when the oscillations are small a simple pendulum is in simple harmonic motion. The solution of Eq. (70) can be carried out in the form (63) where, of course, x is replaced by φ . Assuming, at $t=0$, $\varphi = \varphi_0$ and $\dot{\varphi}_0 = 0$, and after determining the constants of integration, we finally obtain the equation of motion in the form

$$\varphi = \varphi_0 \cos kt.$$

The period of small oscillations of a pendulum is

$$T = \frac{2\pi}{k} = 2\pi \sqrt{\frac{l}{g}}. \quad (71)$$

We see that the value of T does not depend on the initial angle of deflection.

This result holds good only for a small angle φ_0 . It will be found, if we integrate Eq. (69) and assume angle φ not very small, that the value of T depends on φ_0 .

Approximately this dependence has the form

$$T = 2\pi \sqrt{\frac{l}{g}} \left(1 + \frac{\varphi_0^2}{16} \right). \quad (72)$$

From this, for instance, we see that at $\varphi = 0.4$ radians (about 23°), Eq. (71) defines the period with an accuracy of one per cent.

125. Damped Vibration. Let us see how the resistance of a surrounding medium affects vibrations, assuming the resisting force proportional to the first power of the velocity: $R = -\mu v$ (the minus indicates that force R is opposite to v). Let a moving particle be acted upon by a restoring force F and a resisting force R (Fig. 286).

Fig. 286.

Then $F_x = -cx$, $R_x = -\mu v_x = -\mu \frac{dx}{dt}$, and the differential equation of motion is

$$m \frac{d^2x}{dt^2} = -cx - \mu \frac{dx}{dt}.$$

Dividing both sides by m , we obtain

$$\frac{d^2x}{dt^2} + 2b \frac{dx}{dt} + k^2x = 0, \quad (73)$$

where

$$\frac{c}{m} = k^2, \quad \frac{\mu}{m} = 2b. \quad (74)$$

It is easy to verify that k and b have the same dimension (sec^{-1}), which makes it possible to compare them.

Eq. (73) is called the *differential equation of damped vibration*. The solution of Eq. (73) can be found by passing to a new variable z through the equality $x = ze^{-bt}$. Then

$$\frac{dx}{dt} = e^{-bt} \left(\frac{dz}{dt} - bz \right); \quad \frac{d^2x}{dt^2} = e^{-bt} \left(\frac{d^2z}{dt^2} - 2b \frac{dz}{dt} + b^2z \right).$$

Substituting these expressions and the expression of x into Eq. (73), and after the necessary computation, we obtain

$$\frac{d^2z}{dt^2} + (k^2 - b^2)z = 0. \quad (75)$$

Let us consider the case when $k > b$, i.e., when the resistance is small as compared with the restoring force. Introducing the notation

$$\tilde{k} = \sqrt{k^2 - b^2}, \quad (76)$$

we see that Eq. (75) coincides with Eq. (62). Consequently, $z = a \sin(\tilde{k}t + \alpha)$ or, passing to x ,

$$x = ae^{-bt} \sin(\tilde{k}t + \alpha). \quad (77)$$

The expression (77) gives the solution of differential equation (73).

The quantities a and α are constants of integration and are determined by the initial conditions.

Vibrations according to the law (77) are called *damped* because, due to the multiplier e^{-bt} , the value of x decreases with time and tends to zero. A graph of such vibrations is given in Fig. 287 (the curve lies between the broken curves $x = ae^{-bt}$ and $x = -ae^{-bt}$, as $\sin(\tilde{k}t + \alpha)$ cannot exceed unity). The graph shows that the vibrations are not periodic, though they do show a certain repetition. For example, a particle oscillating about a centre O returns to that centre at certain intervals \tilde{T} equal to the period $\sin(\tilde{k}t + \alpha)$. Therefore the quantity

$$\tilde{T} = \frac{2\pi}{\tilde{k}} = \frac{2\pi}{\sqrt{k^2 - b^2}} \quad (78)$$

Fig. 287.

is conventionally called the *period of damped vibration*. Comparing Eqs. (78) and (66), we see that $\tilde{T} > T$, i. e., that resistance to vibration tends to increase the period of the vibration. When, however, the resistance is small ($b \ll k$) the quantity b^2 can be neglected in comparison with \tilde{k}^2 and we can assume $\tilde{T} \approx T$. Thus, a small resistance has no practical effect on the period of vibration.

The time interval between two successive displacements of an oscillating particle to the right or to the left is also equal to \tilde{T} *. Hence, if the maximum displacement x_1 to the right takes place at time t_1 , the second displacement x_2 will be at time $t_2 = t_1 + \tilde{T}$, etc. Then, by Eq. (77) and taking into account that $\tilde{k}\tilde{T} = 2\pi$, we have

$$x_1 = ae^{-bt_1} \sin(\tilde{k}t_1 + \alpha),$$

$$x_2 = ae^{-b(t_1 + \tilde{T})} \sin(\tilde{k}t_1 + \tilde{k}\tilde{T} + \alpha) = x_1 e^{-b\tilde{T}}.$$

Similarly, for any displacement x_{n+1} , we will have $x_{n+1} = x_n e^{-b\tilde{T}}$. Thus we find that the amplitude of vibration decreases in geometric progression. The denominator of this progression $e^{-b\tilde{T}}$ is called the *damping decrement*, and the modulus of its logarithm, i. e., the quantity $-b\tilde{T}$, the *logarithmic decrement*.

It follows from these results that a small resistance has practically no effect on the period of vibration, but gradually damps it by virtue of the amplitude of vibration decreasing according to a law of geometric progression.

When the resistance is large and $b > k$, the solution of Eq. (75) contains no trigonometric functions. The particle no longer oscillates but instead, under the influence of the restoring force, gradually approaches the position of equilibrium. A graph of such motion (if, at $t=0$, $x=x_0$ and $v_0 > 0$) has the form shown in Fig. 288.

Fig. 288.

126. Forced Vibrations. Resonance. Let us consider an important case of vibration where, in addition to a restoring force F , a particle is also subjected to a force Q , varying periodically with time, whose projection on the axis Ox is

$$Q_x = Q_0 \sin pt. \quad (79)$$

* The instants of maximum or minimum x are found from the equation $\frac{dx}{dt} = ae^{-bt} [\tilde{k} \cos(\tilde{k}t + \alpha) - b \sin(\tilde{k}t + \alpha)] = 0$. If at some instant $t=t_1$ the expression in the brackets becomes zero, then, apparently, at times $t_1 + \tilde{T}$, $t_1 + 2\tilde{T}$, etc., it will again become zero.

This force is called a *disturbing force*, and the vibration caused by it is called *forced*. The quantity p in Eq. (79) is called the *frequency of the disturbing force*.

A disturbing force may vary with time according to other laws, but we shall consider only the case of Q_x defined by Eq. (79). This type of disturbing force is called a *periodic force*. An example involving such a force is given in Problem 120 on p. 298.

1. **Undamped Forced Vibration***. Consider the motion of a particle on which, besides the restoring force F , is acting only a disturbing force Q (Fig. 281). The differential equation of motion will be

$$m \frac{d^2x}{dt^2} = -cx + Q_0 \sin pt.$$

Dividing both sides of the equation by m and assuming $Q_0/m = P_0$ and taking into account the expression (61), the equation takes the form

$$\frac{d^2x}{dt^2} + k^2x = P_0 \sin pt. \quad (80)$$

Eq. (80) is the differential equation of undamped forced vibration of a particle. From the theory of differential equations, its solution is $x = x_1 + x_2$, where x_1 is the general solution of the equation without the right side, i.e., the solution of Eq. (62) as given by Eq. (64), and x_2 is a particular solution of the complete equation (80).

Assuming $P \neq k$, let us find the solution of x_2 in the form

$$x_2 = A \sin pt,$$

where A is a constant, such that Eq. (80) becomes an identity. Substituting the expression of x_2 and its second derivative into Eq. (80), we have

$$-p^2 A \sin pt + k^2 A \sin pt = P_0 \sin pt.$$

This equation is satisfied at any t , if $A(k^2 - p^2) = P_0$, or

$$A = \frac{P_0}{k^2 - p^2}.$$

Thus, the required particular solution is

$$x_2 = \frac{P_0}{k^2 - p^2} \sin pt. \quad (81)$$

* The results obtained in this section can be obtained as a special case of Section 2.

As $x = x_1 + x_2$ and the expression for x_1 is given by Eq. (64), the general solution of Eq. (80) takes the final form

$$x = a \sin(kt + \alpha) + \frac{P_0}{k^2 - p^2} \sin pt. \quad (82)$$

where a and α are constants of integration determined by the initial conditions.

Solution (82) shows that in the present case the vibration of a particle consists of: 1) *free vibrations* of amplitude a (depending on the initial conditions) and frequency k called *natural vibrations*, and 2) *forced vibrations* of amplitude A (not depending on the initial conditions) and frequency p .

In practice, due to the inevitable presence of various damping forces, the natural vibrations rapidly disappear. Therefore in this type of motion the forced vibrations defined by Eq. (81) are of primary importance.

The frequency p of forced vibrations is, evidently, equal to the frequency of the disturbing force. The amplitude of this vibration is

$$A = \frac{P_0}{|k^2 - p^2|} = \frac{\delta_0}{\left|1 - \left(\frac{p}{k}\right)^2\right|}, \quad (83)$$

where $\delta_0 = \frac{P_0}{k^2} = \frac{Q_0}{c}$ is the magnitude of the static deflection of the particle under the action of force Q_0 . Thus, A depends on the ratio of the frequency p of the disturbing force to the frequency k of the natural vibrations. A graph of this dependence is given in Fig. 290a (p. 296) (the curve marked $h=0$, the other curves in the diagram showing the dependence of A on p/k with a resisting force).

It can be seen from the graph [or from Eq. (83)] that forced vibrations of different amplitudes can be induced by choosing different ratios between p and k . When $p=0$ (or $p \ll k$), the amplitude is equal to δ_0 (or is very close to it). When p is almost equal to k , the amplitude becomes very large. At $p=k$ (the impressed frequency is equal to the natural frequency) the phenomenon known as *resonance* occurs. This case is not covered by Eqs. (81)-(83), but it can be proved that when resonance takes place the amplitude of forced vibration increases indefinitely as shown in Fig. 291. Finally, when $p \gg k$, the amplitude A is almost zero (vibration virtually stops).

In conclusion it should be noted that at $p < k$, as can be seen from a comparison of Eqs. (79) and (81), the phases of the forced vibrations and the disturbing force always coincide (both are equal to pt). If, however, $p > k$, then by bringing the minus under the

since we can write Eq. (81) in the form:

$$x_2 = \frac{P_0}{p^2 - k^2} \sin(pt - \pi).$$

Thus, at $p > k$, the phase shift between the forced vibrations and the disturbing force is π (when force Q is maximum and is directed to the right, the vibrating particle is in its extreme left position, etc.).

The general properties of forced vibrations, and resonance in particular, are discussed in greater detail at the end of this section (item 4).

2. **Damped Forced Vibrations.** Consider the motion of a particle on which are acting a restoring force F , a damping force R proportional to the velocity (see § 125), and a disturbing force Q . The differential equation of this motion has the form

$$m \frac{d^2x}{dt^2} = -cx - \mu \frac{dx}{dt} + Q_0 \sin pt.$$

Dividing both sides of the equation by m and assuming $\frac{Q_0}{m} = P_0$, and taking into account the expressions (74), we obtain

$$\frac{d^2x}{dt^2} + 2b \frac{dx}{dt} + k^2x = P_0 \sin pt. \quad (84)$$

Eq. (84) is the *differential equation of damped forced vibration of a particle*. Its general solution, as is known, has the form $x = x_1 + x_2$, where x_1 is the general solution of the equation without the right side, i.e., of Eq. (73) [at $k > b$ this solution is given by Eq. (77)], and x_2 is a particular solution of the complete equation (84). Let us find the solution x_2 in the form

$$x_2 = A \sin(pt - \beta),$$

where A and β are constants so chosen that Eq. (84) should become an identity. Differentiating, we obtain

$$\frac{dx_2}{dt} = Ap \cos(pt - \beta), \quad \frac{d^2x_2}{dt^2} = -Ap^2 \sin(pt - \beta).$$

Substituting these expressions of the derivatives and x_2 into the left side of Eq. (84) and introducing for the sake of brevity the notation $pt - \beta = \psi$ (or $pt = \psi + \beta$), we obtain

$$A(-p^2 + k^2) \sin \psi + 2bpA \cos \psi = P_0(\cos \beta \sin \psi + \sin \beta \cos \psi).$$

For this equation to be satisfied at any value of ψ , i.e., at any instant of time, the factors of $\sin \psi$ and $\cos \psi$ in the left and right sides should be separately equal. Hence,

$$A(k^2 - p^2) = P_0 \cos \beta, \quad 2bpA = P_0 \sin \beta.$$

First squaring and adding these equations, and then dividing one by the other, we obtain:

$$A = \frac{P_0}{\sqrt{(k^2 - p^2)^2 + 4b^2p^2}}, \quad \tan \beta = \frac{2bp}{k^2 - p^2}. \quad (85)$$

As $x = x_1 + x_2$, and the expression x_1 is given by Eq. (77), we have the final solution of Eq. (84) in the form

$$x = ae^{-bt} \sin(\tilde{k}t + \alpha) + A \sin(pt - \beta) \quad (86)$$

where a and α are constants of integration determined from the initial conditions, and the expressions for A and β are given by Eqs. (85) and do not depend on the initial conditions.

These vibrations are compounded of *natural* vibration [the first term in Eq. (86); Fig. 289 a] and *forced* vibration [the second term in Eq. (86); Fig. 289 b]. The natural vibration of the particle in such a case was discussed in § 125. It was established that it is transient and is damped fairly quickly, and after a certain interval of time t_t , called the *transient period*, can be neglected*. A curve showing the transient vibration is given in Fig. 289 c. For practical purposes it can thus be assumed that after a certain transient period a particle will vibrate according to the law

$$x = A \sin(pt - \beta). \quad (87)$$

This is steady-state *forced vibration*, a sustained periodic motion with an amplitude A defined by Eq. (85) and a frequency p equal to the impressed frequency. The quantity β characterises the *phase shift* of forced vibration with respect to the disturbing force.

Let us investigate the results obtained. First let us introduce the notation

$$\frac{p}{k} = \lambda, \quad \frac{b}{k} = h, \quad \frac{P_0}{k^2} = \frac{Q_0}{c} = \delta_0, \quad (88)$$

* If, for example, we assume that free vibrations can be neglected from the moment when their amplitude is less than $0.01 A$, then the value of t_t can be determined from the equation $ae^{-bt} = 0.01 A$, or $t_t = \frac{1}{b} \ln \frac{100a}{A}$. We see, thus, that the less the resistance (i.e., the less the value of b) the greater the transient period.

Fig. 289.

where λ is the frequency ratio, h a quantity characterising the damping effect, δ_0 the magnitude of the static deflection of a particle under the action of force Q_0 (for instance, in the oscillation of a load on a spring, δ_0 is equal to the static elongation of the spring caused by Q_0).

Then, dividing the numerator and denominator of Eq. (85) by k^2 , we obtain

$$A = \frac{\delta_0}{\sqrt{(1 - \lambda^2)^2 + 4h^2\lambda^2}}, \quad \tan \beta = \frac{2h\lambda}{1 - \lambda^2}. \quad (89)$$

It can be seen from Eq. (89) that A and β depend on two dimensionless parameters λ and h . Graphs of this relation for certain values of h are given in Fig. 290. The values of δ_0 , λ , and

Fig. 290.

h can be computed for each specific problem from its conditions, and the values of A and β determined from the respective graphs or Eqs. (89). These graphs (and equations) also show that by altering the frequency ratio λ we can induce forced vibrations of different amplitude.

When the resistance is very small (as ordinarily in the atmosphere) and λ is not close to unity, it is possible in Eqs. (89) to assume approximately $h \approx 0$.

In this case we obtain the results of section 1, namely

$$A \approx \frac{\delta_0}{|1 - \lambda^2|}; \quad \beta \approx 0 \text{ (at } \lambda < 1), \quad \beta \approx 180^\circ \text{ (at } \lambda > 1). \quad (90)$$

Let us consider also the following special cases.

1) If the frequency ratio λ is very small ($p \ll k$), then, assuming as an approximation $\lambda \approx 0$, we obtain from Eq. (89) $A \approx \delta_0$. The vibration in this case has an amplitude equal to the static deflection δ_0 , and the phase shift is $\beta = 0$.

2) If the frequency ratio λ is very large ($p \gg k$), A becomes very small. This case is of special interest for the absorption of vibrations in structures, instruments, etc. Assuming the resistance to be small and neglecting $2h\lambda$ and 1 as compared with λ^2 in Eq. (89), we obtain for computing A an approximate formula:

$$A = \frac{\delta}{\lambda^2} = \frac{P_0}{p^2}.$$

3) In all cases of practical interest h is very small. Then, from Eq. (89), if λ is almost unity the amplitude of forced vibrations becomes very large. This phenomenon is called *resonance**.

At resonance we can assume $\lambda = 1$ in Eq. (89), and then

$$A_r = \frac{\delta_0}{2h}, \quad \beta_r = \frac{\pi}{2}. \quad (91)$$

We see that when h is small A_r can become very large.

The resonance condition in which the amplitude of vibration is A_r , like forced vibration in general, does not develop immediately. The development of steady-state vibration is similar to that shown in Fig. 289c. The less the resistance h , the larger the magnitude of A_r , but also the larger the transient period t_r (see footnote on p. 295).

When the damping force, and with it h , tends to zero, the limiting value of the amplitude A_r , as Eq. (91) shows, tends to infinity, as does the transient period t_r . Thus, with no damping force the vibration amplification process in resonance conditions is unlimited and the amplitude increases indefinitely. A graph of resonance vibration is given in Fig. 291. When the damping forces are very small the picture is similar.

3. General Properties of Forced Vibration. It follows from the results obtained above that forced vibration has the following important properties, which distinguish it from the natural vibration of a particle.

1) The amplitude of forced vibration does not depend on the initial conditions. 2) Forced vibration does not die out in the

Fig. 291.

* It can be seen from Eq. (89) that $A = A_{\max}$ when the term in the denominator $f(\xi) = (1 - \xi)^2 + 4h^2 \xi$ (where $\xi = \lambda^2$) is at its minimum. Solving the equation $f'(\xi) = -2(1 - \xi - 2h^2) = 0$, we obtain that A is maximum at $\xi = 1 - 2h^2$, i.e., at $\lambda_r = \sqrt{1 - 2h^2}$. Thus, resonance sets in when λ is a little less than unity. In practice, however, neglecting h^2 , we can assume that $\lambda_r = 1$.

presence of resistance. 3) The frequency of forced vibration is equal to the frequency of the disturbing force and does not depend on the characteristics of the vibrating system (the disturbing force "impresses" its own vibration frequency on the system). 4) Even when the disturbing force Q_0 is small, large forced vibration can be induced if the resistance is small and the frequency p is almost equal to k (resonance). 5) Even if the disturbing force is large, forced vibration can be damped if the frequency p is much larger than k .

Forced vibration, and resonance in particular, plays an important part in many branches of physics and engineering. Lack of balance in working machines and motors, for example, usually causes forced vibration to appear in the machine or its foundation.

The variation of the amplitude of forced vibration can be traced by making a motor for which $p = \omega$, where ω is the angular velocity of rotation (see Problem 120), rotate with different speeds. As ω increases, the amplitude A of the vibrating part (or foundation) grows. When $\omega = k$, resonance appears and the amplitude of the forced vibration is maximum. When ω increases further, the amplitude A decreases, and at $\omega \gg k$, the value of A is virtually zero. Resonance is most undesirable in engineering structures and should be prevented by choosing the frequency ratio p/k so that forced vibration would tend to zero ($p \gg k$).

In radio engineering the reverse is true. Resonance is extremely useful and is used to separate the signals of one radio station from those of all others (tuning).

The design of such instruments as vibrographs, which measure the displacements of vibrating bodies (foundations, machine parts, etc.) and, in particular, seismographs, which record the vibrations of the earth's crust, are based on the theory of forced vibration.

Problem 120. The deflection caused in a beam by the weight of a motor mounted as shown in Fig. 292 is $\delta_{st} = 1$ cm. At how many rpm of the shaft will resonance appear?

Solution. From the result obtained in Problem 118 it follows that the period of natural vibration of the beam is

$$T = 2\pi \sqrt{\frac{\delta_{st}}{g}}.$$

If the centre of gravity of the shaft is not concentric with its axis, a centrifugal force Q_0 will develop (Fig. 292). Its component $Q_x = Q_0 \sin \omega t$ (where ω is the angular velocity of the shaft) is the disturbing force acting on the beam; its frequency is $p = \omega$. Hence, the period of the forced vibration is $T_f = \frac{2\pi}{\omega}$.

Resonance will appear when $T_f = T$, i.e., at

$$\omega_{cr} = \sqrt{\frac{g}{\delta_{st}}} = 31.3 \text{ sec}^{-1}.$$

Hence the critical speed

$$n_{cr} = \frac{30\omega_{cr}}{\pi} = 300 \text{ rpm.}$$

The working speed of the motor should be much greater than n_{cr} .

Problem 121. Analyse the forced vibration of a load attached to a spring (Problem 118) if the upper end A of the spring oscillates vertically according to the law $\xi = a_0 \sin pt$.

Solution. Draw axis Ox as in Problem 118 (see Fig. 283). If we imagine the upper end of the spring displaced from point A downwards by a quantity ξ , the length of the spring will be $l = l_0 - \xi + \delta_{st} + x$. Then $F_x = -c\Delta l = -c(\delta_{st} + x - \xi)$, and the differential equation of motion, neglecting the resistance of the air and taking into account that $P = c\delta_{st}$, will be

$$m \frac{d^2x}{dt^2} = -c(\delta_{st} + x - \xi) + P = -cx + c\xi.$$

Introducing, as in Problem 118, the notation $\frac{c}{m} = k^2$, we obtain

$$\frac{d^2x}{dt^2} + k^2x = k^2a_0 \sin pt.$$

Consequently, the load will experience forced vibration, since, if we assume $b = 0$ and $P_0 = k^2a_0$, the equation coincides with Eq. (80) or (84).

It can be seen from Eq. (88) that in the present case $\delta_0 = a_0$ and $h = 0$. The amplitude of forced vibration and the phase shift are determined by the Eq. (90).

If $p \ll k$ (the top end of the spring oscillates very slowly), then $\lambda \approx 0$ and $A \approx a_0$ and the phase shift $\beta = 0$. The load will oscillate as if the spring were a rigid rod, which physically corresponds to the condition $k \gg p$. At $p = k$ resonance appears and the amplitude increases sharply. If the frequency p becomes larger than k ($\lambda > 1$) the load will vibrate in such a way that it will move down when the end of the spring moves up and vice versa (a phase shift of $\beta = 180^\circ$), and the larger the value of p the smaller the amplitude. Finally, when p is much greater than k ($\lambda \gg 1$) the amplitude $A \approx 0$. The load will remain in the position of static equilibrium (point O) even though the top end of the spring will oscillate with an amplitude a_0 (the frequency of this vibration is so large that the load, as it were, is unable to keep up with it).

Fig. 292.

Chapter 22

MOTION OF A BODY IN THE EARTH'S GRAVITATIONAL FIELD

127. Motion of a Particle Thrown at an Angle to the Horizon in the Earth's Gravitational Field. The problem of motion in the earth's gravitational field arises when the motion of long-range missiles and artificial earth satellites and questions of interplanetary flight are considered. In these cases, when range and height of the path are comparable with the radius of the earth,

it is necessary (unlike the problem considered in § 108) to take into account the change in gravitational force with distance.

We shall consider a moving particle of mass m . Let the particle at the initial time be at a point M_0 on the surface of the earth (Fig. 293) and let it have a velocity \mathbf{v}_0 directed at an angle α to the horizon. Neglecting the resistance of the air (which, for the heights considered, is quite permissible in the first approximation) and assuming the earth to be fixed, we have acting on the moving particle only the gravitational force \mathbf{F} directed towards the centre of the earth. By the law of gravitation (see § 115, Problem 108),

$$F = mg \frac{R^2}{r^2}, \quad (92)$$

where $r = OM$ is the distance of the particle from the centre of the earth, $R = OM_0$ is the value of r for the point of release M_0 , and g is the acceleration of gravity at point M_0 .*

As \mathbf{F} is a central force (§ 116, paragraph 3), the path of the particle is a plane curve, and the motion can be described in polar coordinates $r = OM$ and φ , with the origin (pole) O at the centre of the earth. We shall set the

Fig. 293.

direction of the polar axis Ox later. Let us now write the differential equations of motion of the particle M .

From the law of areas (§ 116), in motion under the action of a central force the moment of the velocity vector \mathbf{v} with respect to a centre O (twice the areal velocity of the particle) is a constant quantity. Thus $m_0(\mathbf{v}) = c$. But from the diagram we see that $m_0(\mathbf{v}) = r v_\varphi$, where $v_\varphi = r \frac{d\varphi}{dt}$ is the lateral velocity of the particle (see § 71). Hence, we obtain the first equation

$$r^2 \frac{d\varphi}{dt} = c. \quad (93)$$

The value of the constant c is determined from the conditions at the point of release M_0 where, it will be readily noticed,

* In Eq. (92), R can have any value larger than the earth's radius. When M_0 is at the surface of the earth, we shall usually consider R to be the radius of the earth's equator $R = 6,378$ km, and $g = g_0 = 9.81$ m/sec² (in all computations g is the absolute acceleration of gravity, not the relative acceleration, which takes into account the earth's rotation. See § 121).

$m_0(\vartheta_0) = Rv_0 \cos \alpha$, whence

$$c = Rv_0 \cos \alpha. \quad (94)$$

The second equation is obtained from the theorem of the change in kinetic energy in its differential form (§ 114):

$$d\left(\frac{mv^2}{2}\right) = dA.$$

To compute dA , note that the infinitesimal displacement of particle M is composed of the radial displacement dr along ϑ_r and the lateral displacement $r d\varphi$ along ϑ_φ (§ 71, Fig. 155). Since the second displacement is perpendicular to F , and taking into account the directions of the force and the displacement, we obtain from Eq. (92)

$$dA = -Fdr = -mgR^2 \frac{dr}{r^2},$$

and the second equation is

$$d\left(\frac{v^2}{2}\right) = gR^2 d\left(\frac{1}{r}\right), \quad (95)$$

where (see § 71)

$$v^2 = v_r^2 + v_\varphi^2 = \left(\frac{dr}{dt}\right)^2 + r^2 \left(\frac{d\varphi}{dt}\right)^2. \quad (96)$$

By integrating the differential equations (93) and (95), we can determine r and φ as functions of time t , i.e., develop the equation of motion of the particle. Let us, instead, find its path directly. To simplify the computation we introduce a new variable u , assuming

$$u = \frac{1}{r}; \quad \frac{du}{d\varphi} = -\frac{1}{r^2} \frac{dr}{d\varphi}. \quad (97)$$

Taking into account Eqs. (97) and (93), we obtain

$$\frac{dr}{dt} = \frac{dr}{d\varphi} \frac{d\varphi}{dt} = -r^2 \frac{du}{d\varphi} \frac{c}{r^2} = -c \frac{du}{d\varphi}; \quad r \left(\frac{d\varphi}{dt}\right) = \frac{c}{r} = cu.$$

Substituting these values into Eq. (96), we have

$$v^2 = c^2 \left[u^2 + \left(\frac{du}{d\varphi}\right)^2 \right],$$

and Eq. (95), after dividing through by $d\varphi$ and computing the derivative of v^2 , takes the form

$$c^2 \left[u \frac{du}{d\varphi} + \frac{du}{d\varphi} \frac{d^2 u}{d\varphi^2} \right] = gR^2 \frac{du}{d\varphi}.$$

Substituting the expression of c from Eq. (94) and eliminating $\frac{du}{d\varphi}$, we finally obtain the differential equation of the path:

$$\frac{d^2u}{d\varphi^2} + u = \frac{g}{v_0^2 \cos^2 \alpha}. \quad (98)$$

The solution of this equation consists of the general solution of the equation without the right side [which coincides with the solution of Eq. (62) for $k=1$] and the particular solution of the equation with the right side, and has the form

$$u = C_1 \sin \varphi + C_2 \cos \varphi + \frac{g}{v_0^2 \cos^2 \alpha},$$

which can be verified by direct substitution; C_1 and C_2 are the constants of integration.

Now let us choose the direction of the polar axis Ox from which the angle φ is measured, such that at $\varphi=0$ the condition $\frac{du}{d\varphi}=0$ would be satisfied (the meaning of this condition will be explained further on). Then, as

$$\frac{du}{d\varphi} = C_1 \cos \varphi - C_2 \sin \varphi,$$

we obtain $C_1=0$, whence, introducing the notation

$$p = \frac{v_0^2 \cos^2 \alpha}{g}, \quad (99)$$

we have $pu = pC_2 \cos \varphi + 1$. Assuming $pC_2 = -e$, where e is a new constant of integration, and passing from u to r , we finally obtain the equation of the path in the form

$$r = \frac{p}{1 - e \cos \varphi}. \quad (100)$$

We know from analytical geometry that Eq. (100) is the equation of a conic section (ellipse, parabola or hyperbola), where p is the focal parameter and e the eccentricity, expressed in polar coordinates whose pole O is one of the foci and whose polar axis is coincident with the axis of symmetry of the curve away from the apex closest to the focus (which explains our choice of the polar axis).

The actual path will depend on the value of the constant of integration e , which we can find from the conditions at the point of release M_0 . Let us denote the size of the unknown angle M_0Ox by β . From Eq. (97) and Fig. 293 it follows that at point M_0

$$\left(\frac{du}{d\varphi}\right)_0 = -\left(\frac{1}{r} \frac{dr}{d\varphi}\right)_0 = -\frac{1}{R} \frac{v_{r0}}{v_{\varphi 0}} = -\frac{1}{R} \tan \alpha.$$

Then the initial conditions are

$$\text{at } t=0, \varphi = -\beta, u = \frac{1}{R}, \frac{du}{d\varphi} = -\frac{1}{R} \tan \alpha.$$

From Eq. (100), and passing again from r to u , we obtain

$$u = \frac{1}{\rho} (1 - e \cos \varphi), \quad \frac{du}{d\varphi} = \frac{e}{\rho} \sin \varphi.$$

Substituting the initial values and replacing ρ by its expression in (99), we arrive at the equations

$$e \cos \beta = 1 - \frac{v_0^2 \cos^2 \alpha}{gR}; \quad e \sin \beta = \frac{v_0^2 \sin 2\alpha}{2gR}. \quad (101)$$

By dividing these equations and then squaring and adding them, we finally obtain

$$\tan \beta = \frac{v_0^2 \sin 2\alpha}{2(gR - v_0^2 \cos^2 \alpha)}, \quad (102)$$

$$e = \sqrt{1 + \frac{v_0^2 \cos^2 \alpha}{g^2 R^2} (v_0^2 - 2gR)}. \quad (103)$$

Eq. (102) defines angle β , i.e., the position of the axis of symmetry of the path with respect to the point of release M_0 . Eq. (103) gives the eccentricity of the path. It shows that the path of a particle is

- a) an ellipse ($e < 1$), if $v_0 < \sqrt{2gR}$;
- b) a parabola ($e = 1$), if $v_0 = \sqrt{2gR}$;
- c) a hyperbola ($e > 1$), if $v_0 > \sqrt{2gR}$.

The velocity $v_p = \sqrt{2gR}$ is called the *parabolic*, or *escape*, *velocity*. Assuming $R = R_0 = 6,378$ km and $g = g_0 = 9.81$ m/sec², we obtain $v_p \approx 11.2$ km/sec. Thus, a body projected from the surface of the earth at any angle to the horizon with an initial velocity $v_0 \geq 11.2$ km/sec will move in a parabola or hyperbola (at $\alpha = 90^\circ$, in a straight line), receding infinitely away from the earth. Velocities of this order are essential for interplanetary travel*. If the velocity is less than the escape velocity, the body will either fall back to earth or become an artificial satellite.

* The velocity necessary for a spaceship to escape the combined pull of the earth and the sun is greater than $\sqrt{2g_0 R_0}$, and for some directions v_0 is about 16.7 km/sec.

The equation of motion of a particle on its path, i.e., its location at any instant, can be derived by substituting for r in Eq. (93) its expression (100) and integrating the new equation.

128. Artificial Earth Satellites. Elliptical Paths. At $v_0 < \sqrt{2gR}$, a body projected from the earth's surface can become an artificial satellite if its path (an ellipse) does not pass through the earth, i.e., if for every point of the path $r \geq R_0$, or $r_{\min} = R_0$, where R_0 is the radius of the equator. As $r_{\min} = OP$ (see Fig. 293), the condition $r_{\min} = R_0$ will be satisfied if point P lies on the surface of the earth and, consequently, coincides with M_0 (see Fig. 294), i.e., when $\beta = \pi$. But Eqs. (101) show that $\beta = \pi$ only at $\alpha = 0$ (or $\alpha = \pi$) and $v_0^2 \geq gR$, since e cannot be negative. Consequently, for a body projected from the earth's surface to become an artificial satellite two conditions must be satisfied:

$$\alpha = 0, \quad \sqrt{2gR} > v_0 \geq \sqrt{gR}. \quad (104)$$

From Eqs. (101) we find that the eccentricity of a satellite orbit at $\alpha = 0$ and $\beta = \pi$ will be

$$e = \frac{v_0^2}{gR} - 1. \quad (105)$$

The velocity $v_c = \sqrt{gR}$, at which $e = 0$ and the satellite follows a circular orbit of radius R , is called the *circular velocity*. For a body projected from the surface of the earth assuming $R = R_0 = 6,378$ km and $g = g_0 = 9.81$ m/sec², the circular velocity $v_c \approx 7,910$ m/sec. At $v_0 > v_c$, a satellite orbit is an ellipse whose eccentricity will increase as v_0 increases (Fig. 294).

Fig. 294.

A body projected from the surface of the earth can never become an artificial satellite if the angle of elevation $\alpha \neq 0$, whatever the initial velocity v_0 (even neglecting the resistance of the air). That is why, for instance, it is impossible

to launch an artificial earth satellite by shooting one from a cannon. A guided rocket capable of lifting a satellite to a required altitude and imparting to it at a point M_0 (Fig. 294) the required velocity v_0 at an angle $\alpha \approx 0$ to the horizon must be used. This was just how the world's first artificial satellites, the Soviet sputniks, were launched.

Finally, the greater the height H of point M_0 above the surface of the earth, the less the resistance of the atmosphere and the longer a satellite's lifetime. It will also be noticed that it becomes possible to project a satellite into orbit at $\alpha \neq 0$.

The greater the elevation H , the less the circular velocity $v_c = \sqrt{gR}$, as $g = g_0 R_0^2 / R^2$ and $R = R_0 + H$, and consequently

$$v_c = \sqrt{gR} = \sqrt{\frac{g_0 R_0^2}{R}} = \sqrt{g_0 R_0} \sqrt{\frac{R_0}{R_0 + H}}.$$

For example, at $H = 0$, $v_c = 7,910$ m/sec; at $H = 500$ km, $v_c = 7,620$ m/sec; at $H = 1,000$ km, $v_c = 7,360$ m/sec, etc. The total energy needed to launch a satellite, though, increases with H . For, denoting the energy per unit of mass by the symbol \tilde{T} , the energy required to boost a satellite to point M_0 (neglecting the resistance of the air) will be $\tilde{T}_1 = 0.5v_{in}^2 = 0.5 \frac{2g_0 R_0 H}{R_0 + H}$ (see Problem 108, p. 263), and the energy needed to impart the orbital velocity will be $\tilde{T}_2 = 0.5v_c^2$. Hence, the total expenditure of energy per unit mass will be

$$\tilde{T} = 0.5 \left(\frac{g_0 R_0^2}{R_0 + H} + \frac{2g_0 R_0 H}{R_0 + H} \right) = 0.5g_0 R_0 \frac{R_0 + 2H}{R_0 + H}$$

and will increase as H increases.

Elliptical Paths. At $\alpha > 0$ and $v_0 < \sqrt{2g_0 R_0}$, a body projected from the surface of the earth will describe an elliptical arc and fall back to the ground. Such elliptical paths are travelled by long-range (intercontinental) ballistic missiles. Let us find the principal characteristics of such paths.

Since axis Ox (see Fig. 293) is the axis of symmetry of the path, the point of impact will be M_1 and the range S will be equal to the arc $\widetilde{M_0 M_1}$, whence

$$S = 2R_0 \beta. \quad (106)$$

where β is defined by Eq. (102) and by convention R_0 is the mean radius of the earth.

The greatest height H of the path is, evidently, $|(r)_{\varphi=0} - R_0|$ or, according to Eqs. (99) and (100),

$$H = \frac{v_0^2 \cos^2 \alpha}{(1 - e) g_0} - R_0, \quad (107)$$

where e is defined by Eq. (103).

The time of flight T can be found from Eq. (93), which, together with Eq. (94), gives

$$dt = \frac{r^2}{c} d\varphi = \frac{r^2}{R_0 v_0 \cos \alpha} d\varphi.$$

Substituting the expression for r from Eqs. (99) and (100) and integrating, we obtain

$$T = \frac{v_0^3 \cos^3 \alpha}{R_0 g_0^2} \int_{-\beta}^{\beta} \frac{d\varphi}{(1 - e \cos \varphi)^2},$$

solving which, we finally have

$$T = \frac{2v_0^3 \cos^3 \alpha}{R_0 g_0^2 (\sqrt{1 - e^2})^3} (z + e \sin z), \quad (108)$$

where

$$z = 2 \arctan \left(\sqrt{\frac{1+e}{1-e}} \tan \frac{\beta}{2} \right). \quad (109)$$

With these formulas and knowing v_0 and the angle of elevation α , we can find the range S , the highest point of the path H , and the time of flight T .

From the practical point of view it is important to determine the minimum velocity v_0^{\min} and the optimum angle of elevation α_{opt} at which the required range $S = 2R_0\beta$ can be obtained.

For this we compute the value of v_0 from Eq. (102):

$$v_0 = \sqrt{\frac{2R_0 g_0 \tan \beta}{\sin 2\alpha + 2 \cos^2 \alpha \tan \beta}}. \quad (110)$$

For a given range (or given angle β) the required velocity depends on the angle of elevation α . Angle α enters only into the denominator of Eq. (110); hence, v_0 is minimum when the denominator is maximum. Equating the derivative of the denominator with respect to α to zero, we find

$$\cos 2\alpha - \sin 2\alpha \tan \beta = 0,$$

whence $\cot 2\alpha_{\text{opt}} = \tan \beta$, and the optimum angle of elevation is

$$\alpha_{\text{opt}} = 45^\circ - \frac{\beta}{2}. \quad (111)$$

That this value of α_{opt} gives v_0^{\min} can be readily verified by the sign of the second derivative. Substituting the value of α_{opt} into Eq. (110), we obtain

$$v_0^{\min} = \sqrt{2R_0 g_0 \frac{\sin \beta}{1 + \sin \beta}}. \quad (112)$$

Eqs. (112) and (111) give the least initial velocity and the optimum angle of elevation for a required range. The height of the path and the time of flight are computed from Eqs. (107) and (108), in which v_0 and α are substituted by their expressions from Eqs. (112) and (111). Table I below gives the characteristics of some optimum elliptical paths computed from these formulas, assuming $R_0 = R_{mean} = 6,370$ km (the accuracy of all quantities in the table is up to 5 units of the last digit).

Table I

Angle β	Range S in km	Necessary initial velocity v_0^{min} in m/sec	Optimum angle of elevation α_{opt}	Height of path H in km	Time of flight T
10°	2,220	4,300	40°	500	12 min 30 sec
20°	4,450	5,650	35°	900	19 min 10 sec
30°	6,670	6,460	30°	1,170	24 min 50 sec
40°	8,900	7,000	25°	1,300	30 min 00 sec
70°	15,570	7,780	10°	900	40 min 10 sec
90°	20,020	7,910	0°	0	42 min 10 sec

Remember that these calculations refer to motion in vacuo and do not take into account the rotation of the earth. In conclusion it should be noted that at small ranges (small angle β) the elliptical arc described by a projectile approaches a parabolic arc. If we take $\sin \beta \approx \beta$ and $2R_0\beta = X$ and in the other equations neglect β in comparison with unity, in the limit all these equations will develop into the corresponding equations of parabolic paths (see § 108). In particular, from Eqs. (111) and (112) we immediately obtain $\alpha_{opt} = \alpha^* = 45^\circ$ and $v_0^{min} = \sqrt{g_0 X^*}$.

PART IV

DYNAMICS OF A SYSTEM AND A RIGID BODY

Chapter 23

INTRODUCTION TO THE DYNAMICS OF A SYSTEM. MOMENTS OF INERTIA OF RIGID BODIES

129. Mechanical Systems. External and Internal Forces. A *mechanical system* is defined as such a collection of material points (particles) or bodies in which the position or motion of each particle or body of the system depends on the position and motion of all the other particles or bodies. We shall thus regard a material body as a system of its particles.

A classical example of a mechanical system is the solar system, all the component bodies of which are connected by the forces of their mutual attraction. Other examples of mechanical systems are machines, or any mechanism whose members are connected with pins, rods, cables, belts, etc., i.e., by holonomic constraints. In this case the bodies of the system are subjected to the reciprocal compressive or tensile forces transmitted through the constraints.

A collection of bodies not connected by interacting forces does not comprise a mechanical system (e.g., a group of flying aircraft). In this book we shall consider only mechanical systems, calling them just "systems" for short.

It follows from the above that the forces acting on the particles or bodies of a system can be subdivided into external and internal forces.

External forces are defined as the forces exerted on the members of a system by particles or bodies not belonging to the given system. *Internal forces* are defined as the forces of interaction between the members of the same system. We shall denote external forces by the symbol F^e , and internal forces by the symbol F^i .*

Both external and internal forces can be either active forces or the reactions of constraints. The division of forces into external and internal is purely relative, and it depends on the extent of the system whose motion is being investigated. In considering the

* Not to be confused with inertia force, which was denoted in the same way in § 119.

motion of the solar system as a whole, for example, the gravitational attraction of the sun acting on the earth is an internal force; in investigating the earth's motion about the sun, the same force is external.

Internal forces possess the following properties:

1. *The geometrical sum (the principal vector) of all the internal forces of a system is zero.* This follows from the third law of dynamics, which states that any two particles of a system (Fig. 295) act on each other with equal and oppositely directed forces F_{12}^i and F_{21}^i , the sum of which is zero. Since the same is true for any pair of particles of a system, then

$$\sum F_k^i = 0. \quad (1)$$

2. *The sum of the moments (the principal moment) of all the internal forces of a system with respect to any centre or axis is zero.* For if we take an arbitrary centre O , it is apparent from Fig. 295 that $m_1(F_{12}^i) + m_2(F_{21}^i) = 0$. The same result holds good for the moments about any axis. Hence, for the system as a whole we have

$$\sum m_o(F_k^i) = 0 \text{ or } \sum m_x(F_k^i) = 0. \quad (2)$$

It does not follow from the above, however, that the internal forces are mutually balanced and do not affect the motion of the system, for they are applied to *different* particles or bodies and may cause their mutual displacement. The internal forces will be balanced only when a given system is a rigid body (see § 3).

Fig. 295.

130. **Mass of a System. Centre of Mass.** The motion of a system depends, besides the acting forces, on its total mass and the distribution of this mass. The *mass of a system* is equal to the arithmetical sum of the masses of all the particles or bodies comprising it*:

$$M = \sum m_k. \quad (3)$$

The distribution of mass is characterised primarily by the location of a point called the centre of mass. *The centre of mass,*

* We shall conventionally denote mass by the same letter M as the moment of a force. Any possibility of confusion is precluded by the fact that when the symbol M denotes moment of a force, it is always provided with a subscript (e.g., M_c , M_x , M_t). In Chapter 29, however, where the symbols of moment and mass intermingle frequently, we shall denote the mass of a system by the symbol \mathcal{M} .

or centre of inertia, of a system is defined as a geometrical point C whose coordinates are given by the equations:

$$x_C = \frac{\sum m_k x_k}{M}, \quad y_C = \frac{\sum m_k y_k}{M}, \quad z_C = \frac{\sum m_k z_k}{M}, \quad (4)$$

where m_k is the mass of a particle of the system, and x_k, y_k, z_k are its coordinates.

If the position of a centre of mass is defined by its radius vector \mathbf{r}_C , we can obtain from Eqs. (4) the following expression

$$\mathbf{r}_C = \frac{\sum m_k \mathbf{r}_k}{M}, \quad (5)$$

where \mathbf{r}_k is the radius vector of a particle of the system.

For a body in a uniform gravitational field, the centre of mass coincides with the centre of gravity. For, if in Eqs. (74) (§ 53) we assume $p_k = m_k g$ and $P = Mg$, where g is the acceleration of gravity, which is constant for all the points of a uniform field, by eliminating g we obtain from Eqs. (74) our formulas (4).

The concepts of centre of gravity and centre of mass, however, are not identical. The concept of centre of gravity, as the point through which the resultant of the forces of gravity passes, has meaning only for a rigid body in a uniform field of gravity. The concept of centre of mass, as a characteristic of the distribution of mass in a system, on the other hand, has meaning for any system of particles or bodies, regardless of whether a given system is subjected to the action of forces or not.

131. Moment of Inertia of a Body About an Axis. Radius of Gyration. The position of centre of mass does not characterise

Fig. 296.

completely the distribution of mass in a system. For if in the system in Fig. 296 the distance h of each of two identical spheres A and B from the axis Oz is increased by the same quantity, the location of the centre of mass will not change, though the dis-

tribution of mass will change and influence the motion of the system (all other conditions remaining the same, the rotation about axis Oz will be slower).

Accordingly, another characteristic of the distribution of mass, called the moment of inertia, is introduced in mechanics. The moment of inertia of a body with respect to a given axis Oz is defined as a scalar quantity equal to the sum of the masses of the

particles of the body, each multiplied by the square of its perpendicular distance from the axis:

$$J_z = \sum m_k h_k^2. \quad (6)$$

It will be shown further on that moment of inertia plays the same part in the rotational motion of a body as mass does in translatory motion, i.e., *moment of inertia is a measure of a body's inertia in rotational motion.*

By Eq. (6), the moment of inertia of a body is equal to the sum of the moments of inertia of all its parts with respect to the same axis. For a material point located at a distance h from an axis, $J_z = mh^2$. The dimension of moment of inertia in the technical system of units is $[J] = \text{kgm} \cdot \text{sec}^2$.

The concept of *radius of gyration* is often employed in calculations. The radius of gyration of a body with respect to an axis Oz is a linear quantity ρ defined by the equation

$$J_z = M\rho^2, \quad (7)$$

where M is the mass of the body.

It follows from the definition that geometrically the radius of gyration is equal to the distance from the axis Oz to a point, such that if the mass of the whole body were concentrated in it the moment of inertia of the point would be equal to the moment of inertia of the whole body.

Knowing the radius of gyration, we can obtain the moment of inertia of a body from Eq. (7) and vice versa.

132. Moments of Inertia of Some Homogeneous Bodies. If we divide a body into elements, in the limit the sum in Eq. (6) will become an integral and we obtain

$$J_z = \int_{(V)} h^2 dm, \quad (8)$$

where the integration is over the whole volume of the body and h depends on the coordinates of the points of the body.

Eq. (8) is convenient in computing the moments of inertia of homogeneous bodies. Let us examine some examples.

1. **Thin Homogeneous Rod of Length l and Mass M .** Let us find its moment of inertia with respect to an axis Az perpendicular to the rod (Fig. 297). If we lay off a coordinate axis Ax along AB , for any line element of length dx we have $h = x$ and its mass $dm = \rho_1 dx$, where $\rho_1 = M/l$ is the mass of a

Fig. 297.

unit length of the rod, and Eq. (8) gives*:

$$J_A = \int_0^l x^2 dm = \varrho_1 \int_0^l x^2 dx = \varrho_1 \frac{l^3}{3}.$$

Substituting the expression for ϱ_1 , we obtain finally

$$J_A = \frac{1}{3} Ml^2. \quad (9)$$

2. Thin Circular Homogeneous Ring of Radius R and Mass M . Let us find its moment of inertia with respect to an axis Cz perpendicular to the plane of the ring through its centre (Fig. 298). As all the points of the ring are at a distance $h_k = R$ from axis Cz , Eq. (6) gives

$$J_C = \sum m_k R^2 = (\sum m_k) R^2 = MR^2.$$

Hence, for the ring

$$J_C = MR^2. \quad (10)$$

Fig. 298.

It is evident that the same result is obtained for the moment of inertia of a cylindrical shell of mass M and radius R with respect to its axis.

3. Circular Homogeneous Disc or Cylinder of Radius R and Mass M . Let us compute the moment of inertia of a circular disc with respect to an axis Cz perpendicular to it through its centre (Fig. 299a). Consider an elemental ring of radius r and width dr . Its area is $2\pi r dr$, and its mass $dm = \varrho_2 2\pi r dr$, where $\varrho_2 = \frac{M}{\pi R^2}$ is the mass of a unit area of the disc. From Eq. (10) we have for the elemental ring

$$dJ_C = r^2 dm = 2\pi \varrho_2 r^3 dr,$$

and for the whole disc

$$J_C = 2\pi \varrho_2 \int_0^R r^3 dr = \frac{1}{2} \pi \varrho_2 R^4.$$

Substituting the expression for ϱ_2 , we obtain finally

$$J_C = \frac{1}{2} MR^2. \quad (11)$$

* Here and further on, J_A denotes the moment of inertia with respect to an axis through A perpendicular to the plane of the cross section in the diagram.

It is evident that the same formula is obtained for the moment of inertia J_z of a homogeneous circular cylinder of mass M and radius R with respect to its axis Cz (Fig. 299b).

4. Rectangular Lamina, Cone, Sphere. Omitting the computations, here are the equations of the moments of inertia of several bodies (the student is invited to deduce these formulas independently):

a) uniform rectangular lamina of mass M with sides of length a and b (the x axis is coincident with side a , the y axis with side b):

$$J_x = \frac{1}{3} M b^2, \quad J_y = \frac{1}{3} M a^2.$$

b) uniform right circular cone of mass M and base radius

R (the z axis is coincident with the axis of the cone):

$$J_z = 0.3 MR^2.$$

c) uniform sphere of mass M and radius R (the z axis is coincident with a diameter):

$$J_z = 0.4 MR^2.$$

The moments of inertia of non-homogeneous and composite bodies can be determined experimentally with the help of appropriate instruments. One such method is given in § 155.

133. Moments of Inertia of a Body About Parallel Axes. The Parallel-Axis (Huygens') Theorem. In the most general case, the moments of inertia of the same body with respect to different axes are different. Let us see how to determine the moment of inertia of a body with respect to any axis if its moment of inertia with respect to a parallel axis through the body is known.

Draw an axis Cz through the centre of mass C of a body, and an axis Oz_1 parallel to it (Fig. 300), denoting the distance between the two axes by the symbol d . By definition we have

$$J_{Oz_1} = \sum m_k h_k^2, \quad J_{Cz} = \sum m_k h'_k{}^2,$$

where h_k is the distance of an arbitrary point B of the body from axis Oz_1 , and h'_k is the distance of the same point from axis Cz . It follows from $\triangle Bae$ that

$$h_k^2 = h'_k{}^2 + d^2 - 2dh'_k \cos \alpha_k.$$

Fig. 299.

Let us draw from point C , as the origin of a coordinate system, axes x and y perpendicular to Cz , such that x intersects with axis Oz_1 . It is evident that $Cx \parallel ae$. Denoting the coordinates of point B as x_k, y_k, z_k , we obtain:

$$h'_k \cos \alpha_k = x_k \quad \text{and} \quad h_k^2 = h'^2_k + d^2 - 2dx_k.$$

Substituting this expression of h_k into the expression for J_{Oz_1} , and taking the common factors d^2 and $2d$ outside the summation signs, we have

$$J_{Oz_1} = \sum m_k h'^2_k + (\sum m_k) d^2 - 2d \sum m_k x_k.$$

The first summation in the right side of the equation is equal to J_{Cz} , and the second to the mass M of the body. Let us find

the value of the third summation. From Eq. (4) we know that, for the coordinates of the centre of mass, $\sum m_k x_k = Mx_C$. But since in our case point C is the origin, $x_C = 0$, and consequently $\sum m_k x_k = 0$. We finally obtain

$$J_{Oz_1} = J_{Cz} + Md^2. \quad (12)$$

Eq. (12) expresses the parallel-axis theorem enunciated by Huygens*: *The moment of inertia of a body with respect to any axis is equal to the moment of inertia of the body with respect to a parallel axis through the centre of*

Fig. 300.

mass of the body plus the product of the mass of the body and the square of the distance between the two axes.

It follows from Eq. (12) that $J_{Oz_1} > J_{Cz}$. Consequently, of all the axes of same direction, the moment of inertia is least with respect to the one through the centre of mass.

The parallel-axis theorem can also be used to determine the moment of inertia of a body with respect to a given axis Oz_1 , if its moment of inertia with respect to any parallel axis Az_2 and the distance d_1 and d_2 of each axis from the body's centre of mass are known. Hence, knowing J_{Az_2} and d_2 , we obtain J_{Cz} from Eq.

* Christian Huygens (1629-1695), celebrated Dutch mechanic, physicist and astronomer. He developed the first pendulum clock. In this connection he studied the vibrations of the compound pendulum (see § 154) and introduced the concept of moment of inertia of a body.

(12) and, applying the same formula, determine the required moment of inertia J_{Oz_1} .

Problem 122. Determine the moment of inertia of a slender rod with respect to an axis Cz perpendicular to it through its centre of mass.

Solution. Draw an axis Az through end A of the rod (see Fig. 297; axis Cz is not shown in it). Then, by Eq. (12),

$$J_C = J_A - Md^2.$$

In our case $d = \frac{l}{2}$, where l is the length of the rod, and J_A is found from Eq. (9). Hence,

$$J_C = \frac{1}{3} Ml^2 - \frac{1}{4} Ml^2 = \frac{1}{12} Ml^2.$$

Problem 123. Determine the moment of inertia of a cylinder with respect to an axis Az_1 through its generator (see Fig. 299b).

Solution. From the parallel-axis theorem, $J_{Az_1} = J_{Cz} + Md^2$. In our case $d = R$, and from Eq. (11) $J_{Cz} = \frac{1}{2} MR^2$.

Substituting these expressions, we obtain

$$J_{Az_1} = \frac{1}{2} MR^2 + MR^2 = \frac{3}{2} MR^2.$$

Chapter 24

THEOREM OF THE MOTION OF THE CENTRE OF MASS OF A SYSTEM

134. The Differential Equations of Motion of a System. Suppose we have a system of n particles. Choosing any particle of mass m_k belonging to the system, let us denote the resultant of all the external forces acting on the particle (both active forces and the forces of reaction) by the symbol F_k^e , and the resultant of all the internal forces by F_k^i . If the particle has an acceleration w_k , then, by the fundamental law of dynamics,

$$m_k w_k = F_k^e + F_k^i.$$

Similar results are obtained for any other particle, whence, for the whole system, we have

$$\left. \begin{aligned} m_1 w_1 &= F_1^e + F_1^i, \\ m_2 w_2 &= F_2^e + F_2^i, \\ &\dots\dots\dots \\ m_n w_n &= F_n^e + F_n^i. \end{aligned} \right\} \quad (13)$$

These equations, from which we can develop the law of motion of any particle of the system, are called *the differential equations of motion of a system* in vector form. Eqs. (13) are differential because $\boldsymbol{w}_k = \frac{d\boldsymbol{v}_k}{dt} = \frac{d^2\boldsymbol{r}_k}{dt^2}$. In the most general case the forces in the right side of the equations depend on the time, the coordinates of the particles of the system, and their velocities (see §§ 99 and 107).

By projecting Eqs. (13) on coordinate axes, we can obtain the differential equations of motion of a given system in terms of the projections on these axes.

The complete solution of the principal problem of dynamics for a system would be to develop the equation of motion for each particle of the system from the given forces by integrating the corresponding differential equations. For two reasons, however, this solution is not usually employed. Firstly, the solution is too involved and will almost inevitably lead into insurmountable mathematical difficulties. Secondly, in solving problems of mechanics it is usually sufficient to know certain overall characteristics of the motion of a system, without investigating the motion of each particle. These overall characteristics can be found with the help of the *general theorems* of systems dynamics, which we shall now study.

The main application of Eqs. (13) or their corollaries will be to develop the respective general theorems.

135. Theorem of the Motion of Centre of Mass. In many cases the nature of the motion of a system (especially of a rigid body) is completely described by the law of motion of its centre of mass. To develop this law, let us take the equations of motion of a system (13) and add separately their left and right sides. We obtain

$$\sum m_k \boldsymbol{w}_k = \sum \boldsymbol{F}_k^e + \sum \boldsymbol{F}_k^i. \quad (14)$$

Let us transform the left side of the equation. For the radius vector of the centre of mass we have, from Eq. (5),

$$\sum m_k \boldsymbol{r}_k = M \boldsymbol{r}_C.$$

Taking the second derivative of both sides of this equation with respect to time, and noting that the derivative of a sum equals the sum of the derivatives, we find

$$\sum m_k \frac{d^2 \boldsymbol{r}_k}{dt^2} = M \frac{d^2 \boldsymbol{r}_C}{dt^2}$$

or

$$\sum m_k \boldsymbol{w}_k = M \boldsymbol{w}_C. \quad (15)$$

where w_c is the acceleration of the centre of mass of the system. As the internal forces of a system give (see § 129) $\sum F_k^i = 0$, by substituting all the developed expressions into Eq. (14), we obtain finally

$$Mw_c = \sum F_k^e. \quad (16)$$

Eq. (16) states the theorem of the motion of the centre of mass of a system. Its form coincides with that of the equation of motion of a particle [§ 100, Eq. (3)] of mass $m = M$ where the acting forces are equal to F_k^e . We can therefore formulate the theorem of the motion of the centre of mass as follows: *The centre of mass of a system moves as if it were a particle of mass equal to the mass of the whole system to which are applied all the external forces acting on the system.*

Projecting both sides of Eq. (16) on the coordinate axes, we obtain

$$M \frac{d^2 x_c}{dt^2} = \sum F_{kx}^e, \quad M \frac{d^2 y_c}{dt^2} = \sum F_{ky}^e, \quad M \frac{d^2 z_c}{dt^2} = \sum F_{kz}^e. \quad (16')$$

These are the differential equations of motion of the centre of mass in terms of the projections on the coordinate axes.

The theorem is valuable for the following reasons:

1) It justifies the use of the methods of particle dynamics. It follows from Eqs. (16') that the solutions developed on the assumption that a given body is equivalent to a particle define the law of motion of the centre of mass of that body. Thus, these solutions have a concrete meaning.

In particular, if a body is being translated, its motion is completely specified by the motion of its centre of mass, and consequently, a body in translatory motion can always be treated as a particle of mass equal to the mass of the body. In all other cases, a body can be treated as a particle only when the position of its centre of mass is sufficient to specify the position of the body.

2) The theorem makes it possible, in developing the equation of motion for the centre of mass of any system, to ignore all unknown internal forces. This is of special practical value.

136. The Law of Conservation of Motion of Centre of Mass. The following important corollaries arise from the theorem of the motion of centre of mass:

1) Let the sum of the external forces acting on a system be zero:

$$\sum F_k^e = 0.$$

It follows, then, from Eq. (16) that $\boldsymbol{w}_C = 0$ or $\boldsymbol{v}_C = \text{const.}$

Thus, if the sum of all the external forces acting on a system is zero, the centre of mass of that system moves with a velocity of constant magnitude and direction, i.e., uniformly and rectilinearly. In particular, if the centre of mass was initially at rest it will remain at rest. The action of the internal forces, we see, does not affect the motion of the centre of mass.

2) Let the sum of the external forces acting on a system be other than zero, but let the sum of their projections on one of the coordinate axes (the x axis, for instance), be zero:

$$\sum F_{kx}^e = 0.$$

The first of Eqs. (16'), then, gives

$$\frac{d^2 x_C}{dt^2} = 0 \quad \text{or} \quad \frac{dx_C}{dt} = v_{Cx} = \text{const.}$$

Thus, if the sum of the projections on an axis of all the external forces acting on a system is zero, the projection of the velocity of the centre of mass of the system on that axis is a constant quantity. In particular, if at the initial moment $v_{Cx} = 0$, it will remain zero at any subsequent instant, i.e., the centre of mass of the system will not move along the x axis ($x_C = \text{const.}$).

The above results express the law of conservation of motion of the centre of mass of a system. Let us examine some cases of its application.

a) Motion of the Centre of Mass of the Solar System. Since in practice the attraction of the stars can be neglected, we may assume that there are no external forces acting on the solar system. Hence, in the first approximation, its centre of mass is in uniform rectilinear motion through space.

b) Action of a Force Couple on a Body (see, for example, Fig. 43). If a force couple ($\boldsymbol{F}, \boldsymbol{F}'$) starts acting on a body, the geometrical sum of these external forces will be zero ($\boldsymbol{F} + \boldsymbol{F}' = 0$). Consequently, if the centre of mass C of a system was initially at rest, it must remain at rest after the couple is applied. Thus, no matter to what part of a free rigid body a couple is applied, the body will start rotating about its centre of mass (see § 19).

c) Motion on a Horizontal Plane. In the absence of friction a person would be unable to walk along a horizontal plane with the help of his muscular effort (internal forces) alone, as the sum of the projections on any horizontal axis Ox of all the external forces acting on the person (the force of gravity and reaction of the plane) would be zero and his centre of mass would not move parallel to the plane ($x_C = \text{const.}$).

If, for example, he made a step forward with his right foot, his left one would slip back and his centre of mass would remain at rest. With friction, though, the slipping of the left foot would be opposed by a frictional force directed *forward*. This would be the external force making it possible for the person to move in the direction of its action, i.e., forward.

Something similar takes place in the motion of a locomotive or motor car. The pressure of the boiler steam or engine gases

Fig. 301.

This external force makes the centre of mass of the steam engine or motor car move to the right. When this force is absent, or when it is not sufficient to overcome the opposition to the rotation of the driven wheels*, motion does not take place. The driving wheels will slip without any forward motion.

2) **Braking** Braking is effected by pressing a brake shoe to a drum connected rigidly with a rolling wheel. The frictional force developing between the shoe and drum is an internal force, and alone it cannot alter the motion of the centre of mass, i.e., it cannot stop, say, a train or car. The friction of the shoe on the drum, however, retards the rotation of the wheel around its axis and thereby increases the friction of the wheel on the rail or road, which is directed against the motion. This external force will retard the motion of the centre of mass of the vehicle, i.e., produce the braking effect (see Problem 148, § 156).

137. Solution of Problems. The theorem of the motion of the centre of mass is useful to develop the equation of motion of the mass centre if the external forces are known, and conversely, to determine the principal vector of the external forces acting on a system if the equation of motion of the mass centre is known. The first problem was already studied in particle

* The torque does not act on the driven wheel. Acting on it is a force applied at its axis, which tends to move the wheel together with its point of contact A with the ground forward. The frictional force acting on this wheel is directed in the opposite direction and opposes the motion.

dynamics. Examples of solutions of the second problem are examined below.

The theorem makes it possible to exclude all the internal forces from consideration. This suggests that in investigating a system it should be so chosen as to make some of the immediately unknown forces *internal* with respect to the system.

Whenever the law of conservation of motion of the centre of mass applies, the theorem makes it possible to determine the displacement of any part of the system if the displacement of another part is known.

We have proved that when $\sum F_{kx}^e = 0$ and at the initial moment $v_{Cx} = 0$, $x_C = \text{const.}$ throughout the motion of the system. Let us have a system of three bodies of masses m_1, m_2, m_3 , the initial coordinates of whose centres are x_1, x_2, x_3 . If under the action of any internal (or external) forces the bodies perform absolute displacements the projections of which on the x axis are ξ_1, ξ_2, ξ_3 , the respective coordinates will be $x_1 + \xi_1, x_2 + \xi_2, x_3 + \xi_3$. The coordinate of the centre of mass x_C of the whole system in the initial and final positions will then be:

$$x_{C_0} = \frac{m_1 x_1 + m_2 x_2 + m_3 x_3}{M}; \quad x_{C_1} = \frac{m_1 (x_1 + \xi_1) + m_2 (x_2 + \xi_2) + m_3 (x_3 + \xi_3)}{M}$$

As $x_C = \text{const.}$, $x_{C_0} = x_{C_1}$, and consequently,

$$m_1 \xi_1 + m_2 \xi_2 + m_3 \xi_3 = 0, \quad (17)$$

or

$$\rho_1 \xi_1 + \rho_2 \xi_2 + \rho_3 \xi_3 = 0. \quad (17')$$

Thus, when the law of conservation of motion of the centre of mass holds good for displacements along an axis Ox , the algebraic sum of the products of the masses (or weights) of the bodies of the system on the projections of the absolute displacements of their centres of mass must be zero, if at the initial moment $v_{Cx} = 0$. In computing ξ_1, ξ_2, \dots attention should always be paid to their signs.

Problem 124. Two men of weights p_A and p_B are seated in the bow and stern of a boat of weight P at a distance l from each other (Fig. 302). Neglecting the resistance of the water, determine the direction and size of the displacement of the boat if the men change places.

Solution. In order to exclude from consideration the unknown forces of friction of their shoe soles on the bottom of the boat and the muscular

Fig. 302.

efforts of the men, we consider the boat and the men in it as one system, and the mentioned forces become internal. The external forces acting on the boat are the vertical forces P, p_A, p_B , and N . Hence, $\sum F_{kx}^e = 0$, and, as at the initial moment $v_{Cx} = 0$, $x_C = \text{const.}$ Consequently, the absolute displacements of all the bodies are governed by the formula (17).

Denoting the boat and the men in their initial and final positions, we find that the displacement of the boat $\xi_b = x$. Furthermore, the absolute displacement of the first man is $\xi_A = x + l$, the absolute displacement of the second man is BB_1 , and the projection of the latter displacement on the x axis is $\xi_B = -(l - x)$. Hence, from Eq. (17'),

$$Px + p_A(x + l) + p_B[-(l - x)] = 0,$$

whence we find the displacement of the boat:

$$x = \frac{p_B - p_A}{P + p_A + p_B} l.$$

If $p_B > p_A$, $x > 0$, i.e., the boat will move to the right; if $p_B < p_A$, the boat will move to the left. If $p_B = p_A$, the boat will remain at rest.

The procedure mentioned above is important enough to repeat the formulation: in solving problems of this type, the system to be investigated must be chosen so that the immediately unknown forces would be internal.

Problem 125. The centre of gravity of the shaft of the motor in Fig. 303 is located at a distance $AB = a$ from the axis of rotation. The shaft is of weight p , and the weight of all other parts of the motor is P . Deduce the law of motion of the motor on a smooth horizontal surface if the shaft rotates with a uniform angular velocity ω . Also determine the maximum stress that will be developed in a bolt D fastening the motor to the surface.

Solution. In order to eliminate the forces rotating the shaft by making them internal, consider the motor with the shaft as a single system.

1) For the motor standing freely on the plane, all the forces acting on it are vertical and, as in the previous problem, the law of conservation of the motion of the centre of mass parallel to axis Ox will apply. Show the motor in an arbitrary position, assuming as initial the position in which points B and A are on the same vertical (on the y axis). Then in the arbitrary position $\xi_A = x$, $\xi_B = x + a \sin \varphi$. Hence, taking into account that $\varphi = \omega t$, we find from Eq. (17')

$$Px + p(x + a \sin \omega t) = 0,$$

whence

$$x = -\frac{pa}{P + p} \sin \omega t.$$

Thus, the motor will perform simple harmonic motion with an angular frequency ω .

2) When the motor is fastened, the horizontal reaction R_x of the bolt, by the first of Eqs. (16'), will be

$$R_x = M \frac{d^2 x_C}{dt^2}, \text{ where } x_C = \frac{Px_A + px_B}{Mg}.$$

In this case point A is fixed, and $x_A = h$ ($h = \text{const.}$) and $x_B = h + a \sin \omega t$. Differentiating the expression of x_C and multiplying it by M , where M is the mass of the whole system, we obtain

$$R_x = M \frac{d^2 x_C}{dt^2} = \frac{p}{g} \frac{d^2 x_B}{dt^2} = -\frac{pa\omega^2}{g} \sin \omega t.$$

Fig. 303.

The pressure on the bolt is equal to $|R_x|$ in magnitude and opposite in direction. Its maximum value will be $\frac{pa\omega^2}{g}$.

Problem 126. Crank AB of length r and weight p of the mechanism in Fig. 304 rotates with a constant angular velocity ω and actuates the slotted bar and the piston D connected to it. The total weight of the bar and piston is P . Acting on the piston during the motion is a constant force Q . Neglecting friction, determine the maximum horizontal pressure of the crank on its axle A .

Fig. 304.

Solution. In order to eliminate the forces rotating the crank and the pressure exerted on it by the slotted bar, consider the motion of the system as a whole. Denoting the horizontal reaction of the axle A by R_x , we have from the first of Eqs. (16')

$$M \frac{d^2 x_C}{dt^2} = R_x - Q,$$

where, by Eqs. (4), $Mx_C = m_1 x_1 + m_2 x_2$.

In our case

$$m_1 = \frac{p}{g}, \quad x_1 = \frac{r}{2} \cos \omega t; \quad m_2 = \frac{P}{g}, \quad x_2 = a + r \cos \omega t,$$

as $\varphi = \omega t$. We finally obtain

$$R_x = Q + M \frac{d^2 x_C}{dt^2} = Q - \frac{r\omega^2}{g} \left(\frac{p}{2} + P \right) \cos \omega t.$$

The pressure on the shaft is equal in magnitude to $|R_x|$ and oppositely directed. The maximum pressure will be at $\varphi = 180^\circ$ and will be equal to $Q + \frac{r\omega^2}{g} \left(\frac{p}{2} + P \right)$.

Chapter 25

THEOREM OF THE CHANGE IN THE LINEAR
MOMENTUM OF A SYSTEM

138. **Linear Momentum of a System.** The linear momentum, or simply the momentum, of a system is defined as the vector quantity Q equal to the geometric sum (the principal vector) of the momenta of all the particles of the system (Fig. 305):

$$Q = \sum m_k v_k. \quad (18)$$

It can be seen from the diagram that, irrespective of the velocities of the particles (provided that they are not parallel) the momentum vector can take any value, or even be zero when the polygon constructed with the vectors $m_k v_k$ as its sides is closed. Consequently, the quantity Q does not characterise the motion of the system completely.

Fig. 305.

Let us develop a formula with which it is much more convenient to compute Q and also to explain its meaning. It follows from Eq. (5) that

$$\sum m_k r_k = M r_c.$$

Differentiating both sides with respect to time, we obtain

$$\sum m_k \frac{dr_k}{dt} = M \frac{dr_c}{dt} \quad \text{or} \quad \sum m_k v_k = M v_c,$$

whence we find that

$$Q = M v_c, \quad (19)$$

i.e., the momentum of a system is equal to the product of the mass of the whole system and the velocity of its centre of mass. This equation is especially convenient in computing the momentum of rigid bodies.

It follows from Eq. (19) that, if the motion of a body (or a system) is such that the centre of mass remains motionless, the momentum of the body is zero. Thus, the momentum of a body rotating about a fixed axis through its centre of mass is zero (the polygon in Fig. 305 is closed).

If, on the other hand, a body has relative motion, the quantity Q will not characterise the rotational component of the

motion about the centre of mass. Thus, for a rolling wheel, $\mathbf{Q} = M\mathbf{v}_C$, regardless of how the wheel rotates about its centre of mass C .

We see, therefore, that *momentum characterises only the translatory motion of a system*, which is why it is often called *linear momentum*. In relative motion, the quantity \mathbf{Q} characterises only the translatory component of the motion of a system together with its centre of mass.

139. Theorem of the Change in Linear Momentum. Consider a system of n particles. Writing the differential equations of motion (13) for this system and adding them, we obtain

$$\sum m_k \mathbf{w}_k = \sum \mathbf{F}_k^e + \sum \mathbf{F}_k^i.$$

From the property of internal forces the last summation is zero. Furthermore,

$$\sum m_k \mathbf{w}_k = \frac{d}{dt} (\sum m_k \mathbf{v}_k) = \frac{d\mathbf{Q}}{dt},$$

and we finally have

$$\frac{d\mathbf{Q}}{dt} = \sum \mathbf{F}_k^e. \quad (20)$$

Eq. (20) states the theorem of the change in the linear momentum of a system in differential form: *The derivative of the linear momentum of a system with respect to time is equal to the geometrical sum of all the external forces acting on the system.*

In terms of projections on cartesian axes we have

$$\frac{dQ_x}{dt} = \sum F_{kx}^e, \quad \frac{dQ_y}{dt} = \sum F_{ky}^e, \quad \frac{dQ_z}{dt} = \sum F_{kz}^e. \quad (21)$$

Let us develop another expression for the theorem. Let the momentum of a system be \mathbf{Q}_0 at time $t=0$, and at time t , let it be \mathbf{Q}_1 . Multiplying both sides of Eq. (20) by dt and integrating, we obtain

$$\mathbf{Q}_1 - \mathbf{Q}_0 = \sum \int_0^t \mathbf{F}_k^e dt,$$

or

$$\mathbf{Q}_1 - \mathbf{Q}_0 = \sum \mathbf{S}_k^e, \quad (22)$$

as the integrals to the right give the impulses of the external forces.

Eq. (22) states the theorem of the change in the linear momentum of a system in integral form: *The change*

in the linear momentum of a system during any time interval is equal to the sum of the impulses of the external forces acting on the body during the same interval of time.

In terms of projections on cartesian axes we have

$$\left. \begin{aligned} Q_{1x} - Q_{0x} &= \sum S_{kx}^e \\ Q_{1y} - Q_{0y} &= \sum S_{ky}^e \\ Q_{1z} - Q_{0z} &= \sum S_{kz}^e \end{aligned} \right\} \quad (23)$$

Let us show the connection between this theorem and the theorem of the motion of centre of mass. As $\mathbf{Q} = M\mathbf{v}_c$, by substituting this expression into Eq. (20) and taking into account that $\frac{d\mathbf{v}_c}{dt} = \mathbf{w}_c$, we obtain $M\mathbf{w}_c = \sum \mathbf{F}_k^e$, i.e., Eq. (16).

Consequently, the theorem of the motion of centre of mass and the theorem of the change in the momentum of a system are, in effect, two forms of the same theorem. Whenever the motion of a rigid body (or system of bodies) is being investigated, both theorems may be used, though Eq. (16) is usually more convenient.

For a continuous medium (a fluid), however, the concept of centre of mass of the whole system is virtually meaningless, and the theorem of the change in the momentum of a system is used in the solution of such problems. This theorem is also very useful in investigating the theory of impact (Chapter 31) and jet propulsion (§ 142).

The practical value of the theorem is that it enables us to exclude from consideration the immediately unknown internal forces (for instance, the reciprocal forces acting between the particles of a liquid).

140. The Law of Conservation of Linear Momentum. The following important corollaries arise from the theorem of the change in the momentum of a system:

1) Let the sum of all the external forces acting on a system be zero:

$$\sum \mathbf{F}_k^e = 0.$$

It follows from Eq. (20) that in this case $\mathbf{Q} = \text{const.}$ Thus, if the sum of all the external forces acting on a system is zero, the momentum vector of the system is constant in magnitude and direction.

2) Let the external forces acting on a system be such that the sum of their projections on any axis Ox is zero:

$$\sum F_{kx}^e = 0.$$

It follows from Eqs. (21) that in this case $Q_x = \text{const.}$ Thus, if the sum of the projections on any axis of all the external forces acting on a system is zero, the projection of the momentum of that system on that axis is a constant quantity.

These results express the law of conservation of the linear momentum of a system. It follows from the above that internal forces are incapable of changing the total momentum of a system. Let us consider some examples.

a) Recoil. If a rifle and the bullet in its barrel are considered as one system, the pressure of the gases during the shot will be an internal force incapable of changing the total momentum of the system. Therefore, as the gases acting on the bullet impart to it a certain momentum in the direction of the muzzle, they must at the same time impart an identical momentum to the rifle in the opposite direction, and the rifle "kicks". This is the phenomenon of recoil well known in artillery.

b) Propeller propulsion. A rotating propeller or screw throws back a certain mass of air (or water) along its axis. If this backward-moving mass and the moving aircraft (or ship) are considered as one system, the forces of interaction between the propeller and the medium are internal and cannot change the total momentum of the system. Therefore, the flowback of air (water) causes the aircraft (or the vessel) to receive a corresponding forward velocity, such that the total momentum of the system remains zero, since it was zero before motion began.

The action of oars or paddle-wheels is of the same nature.

c) Reaction Propulsion. In a reaction-propelled vehicle (e.g., a rocket), the gaseous products of combustion of a fuel are ejected with a high speed from the rear end (or the nozzle of a jet engine). The pressure caused by the gases is an internal force and it cannot change the total momentum of the rocket-combustion products system. But as the ejected gases possess a certain backward-directed momentum, the rocket receives a corresponding forward velocity. The magnitude of this velocity will be determined in § 142.

Note that in propeller propulsion motion is imparted to, say, an aircraft by throwing back the particles of the fluid in which it is moving. In a vacuum such propulsion is impossible. In reaction propulsion, motion is imparted by the ejection of a working fluid produced in the engine itself (the products of combustion), and motion is possible both in the air and in vacuum.

141. Solution of Problems. The theorem of the change in linear momentum is usually employed in studying the motion of a medium (a liquid or gas). Application of the theorem eliminates

all the internal forces from the consideration. Therefore, the investigated system should be so chosen that all or part of the immediately unknown forces would be internal.

The law of conservation of momentum is conveniently used in cases when the velocity of one part of a system has to be determined from the change in the translatory velocity of another part of the system. In particular, the law is widely used in the theory of impact.

Problem 127. A bullet of weight p fired horizontally with a velocity u hits a box of sand standing on a truck (Fig. 306). What velocity will the truck receive as a result of the impact if its weight together with the box of sand is P ?

Solution. Consider the bullet and the truck as one system. This enables us to exclude the forces generated when the bullet hits the sand. The sum of the projections of the external forces on the horizontal axis Ox is zero. Consequently, $Q_x = \text{const.}$, or $Q_{0x} = Q_{1x}$, where Q_0 is the momentum of the system before the impact, and Q_1 after the impact. As the truck was motionless before the impact, $Q_{0x} = \frac{p}{g} u$.

Fig. 306.

After the impact the truck and bullet are moving with the same velocity v . Then

$$Q_{1x} = \frac{p + P}{g} v,$$

and equating the right sides of the expressions for Q_{0x} and Q_{1x} , we obtain

$$v = \frac{p}{p + P} u.$$

Problem 128. Determine the recoil of a gun if its barrel is horizontal, the weight of the recoiling parts is P , the weight of the shell is p , and the muzzle velocity of the shell is u .

Fig. 307.

Solution. To exclude the unknown forces developed by the pressure of the gases, consider the shell and the gun as one system. Neglecting the resistance to the recoil during the motion of the shell in the bore, we find that the sum of the projections of the applied external forces on the axis Ox is zero (Fig. 307). Hence, $Q_x = \text{const.}$ and, since before the shot the system was motionless ($Q_0 = 0$), for any moment of time $Q_x = 0$.

If the velocity of the recoiling parts at the final instant is v , then the absolute velocity of the shell at that moment is $u + v$. Consequently,

$$Q_x = \frac{P}{g} v_x + \frac{p}{g} (u_x + v_x) = 0, \quad (a)$$

whence we find

$$v_x = -\frac{\rho}{\rho + P} u_x.$$

If we knew the absolute muzzle velocity u_a of the shell, we could have substituted u_{ax} for $u_x + v_x$ in equation (a), whence

$$v_x = -\frac{\rho}{P} u_{ax}.$$

The minus sign in both cases means that v is in the opposite direction of u .

Note that in calculating the total momentum of a system the *absolute* velocities of its parts should be considered.

Problem 129. Force of a Jet of Water. A jet of water of diameter $d = 4$ cm is discharged from a nozzle with a velocity $u = 10$ m/sec and impinges normally against a fixed vertical wall (Fig. 308). Neglecting the compression in the jet, determine the force of the water on the wall.

Solution. To exclude the internal forces of interaction of the water particles between each other at the time of impact, apply the first of Eqs. (23)

$$Q_{1x} - Q_{0x} = \sum S_{kx}^e \quad (a)$$

to the part of the jet filling the volume abc at the given instant. Let us calculate for this volume the difference $Q_{1x} - Q_{0x}$ for a certain time interval t_1 . During this interval, the volume of water will occupy configuration $a_1b_1c_1$, and the value of Q_x will decrease by mu , where m is the mass of volume aa_1 . The liquid filling

volumes bb_1 and cc_1 moves normally to axis Ox and therefore does not increase the value of Q_x . As we have only Q_x decreasing,

$$Q_{1x} - Q_{0x} = -mu.$$

Reaction R of the wall will be the only external force acting on the given volume and giving a projection on axis x . Assuming $R = \text{const.}$, we obtain

$$\sum S_{kx}^e = R_x t_1 = -R t_1,$$

and equation (a) gives

$$mu = R t_1. \quad (b)$$

Now compute m . As the displacement $aa_1 = ut_1$,

$$m = \frac{\gamma}{g} \frac{\pi d^2}{4} ut_1,$$

where γ is the weight of a unit volume, and consequently, $\frac{\gamma}{g}$ is the mass of a unit volume of the liquid. Substituting this value into equation (b) and taking into account that for water $\gamma = 1,000$ kg/m³, we finally obtain

$$R = \frac{\gamma}{g} \frac{\pi d^2}{4} u^2 = 12.8 \text{ kg.}$$

The pressure of the water on the wall is equal to this value.

Fig. 308.

142. Bodies Having Variable Mass. Motion of a Rocket. In classical mechanics, the mass of every particle or point of a moving system is considered to be a constant. In some cases, however, the number of particles in a given system or body may change with time (particles may be discharged from a body or added to it from outside). As a result the total weight of a given body will change. We have already examined problems involving the addition or subtraction of finite masses (Problems 127 and 128 in the previous section, and Problem 94 in § 103). In this section we shall examine another case of considerable practical importance, when the process of separation of particles from, or their addition to, a body takes place continuously. A body whose mass M changes continuously with time thanks to the addition of particles to it or their ejection from it, is said to have a *variable mass*.* For a body having variable mass

$$M = F(t),$$

where $F(t)$ is a continuous function of time.

To such bodies belong rockets and jet aircraft, whose masses decrease more or less continuously as the fuel burns out.

If we can neglect the size of a moving body as compared with the distance travelled, it can be considered as a particle having variable mass.

Let us develop the equation of motion for a rocket whose mass continually decreases, considering it as a particle having variable mass in the sense described above. Let u denote the velocity relative to the rocket of the burned gas issued from the rocket. To exclude the forces ejecting the gas and to make them internal, let us consider at any instant t the system consisting of the rocket itself and a particle issuing from it during a time interval dt (Fig. 309). The mass μ of this particle is equal in magnitude to the quantity dM by which the mass of the rocket changes during the interval dt . As M is a decreasing quantity, $dM < 0$, and consequently $\mu = |dM| = -dM$.

For this system, Eq. (20) may be written in the form

$$dQ = F^e dt, \quad (24)$$

where F^e is the geometrical sum of the external forces acting on the rocket.

* Variable mass as treated here has nothing in common with variable mass as treated in the mechanics of the theory of relativity. Here it is due to the change in the number of particles in a given body.

Fig. 309.

If the velocity \mathbf{v} of the rocket changes by $d\mathbf{v}$ during the time interval dt , the momentum of the system will receive an increment $M d\mathbf{v}$. The ejected particle will receive during this time an additional velocity \mathbf{u} , and the momentum of the system will increase by $\mathbf{u}dM = -\mathbf{u}dM$. Consequently, $d\mathbf{Q} = M d\mathbf{v} - \mathbf{u}dM$. Substituting this expression into Eq. (24) and dividing through by dt , we obtain

$$M \frac{d\mathbf{v}}{dt} = \mathbf{F}^e + \mathbf{u} \frac{dM}{dt}. \quad (25)$$

Eq. (25) states in vector form *the differential equation of motion of a particle having variable mass*, known also as *Meshchersky's equation*.*

Since the dimension of the second component in the right side of Eq. (25) is that of force, denoting it by the symbol Φ , we may write the equation in the form

$$M \frac{d\mathbf{v}}{dt} = \mathbf{F}^e + \Phi. \quad (26)$$

Thus, the so-called reaction effect is produced by an additional force Φ , called *the reaction force*, or *thrust*, acting on a moving rocket.

The quantity $\frac{dM}{dt}$ is equal in magnitude to the mass of the fuel burned out in a unit of time, i.e., the per-second expenditure of fuel G_{sec} . Thus, taking into account the sign,

$$\frac{dM}{dt} = -G_{\text{sec}},$$

whence

$$\Phi = -\mathbf{u}G_{\text{sec}}, \quad (27)$$

i.e., *the thrust is equal to the product of the per-second expenditure of fuel and the relative velocity of the exhaust gases and is directed opposite to that velocity*.

Note. These results would be exact if the ejected particles did not interact with each other (as if they were pellets fired in rapid succession, for example). Actually, though, the exhaust gases are discharged in a continuous stream and the particles exert reciprocal forces on each other. Therefore, in atmospheric flight a rocket will additionally be subjected to a force $p_g \sigma$ in the direction of its motion and a force $p_a \sigma$ in the opposite direction, where σ is the area of the exit nozzle, p_g is the pressure of the exit gases over that area, and p_a is the atmospheric pressure. As $p_g > p_a$, the thrust will be larger than given by Eq. (27) by the amount $(p_g - p_a) \sigma$ (for flight in vacuum, $p_a = 0$). This

* I. V. Meshchersky (1859-1935). An outstanding Russian scholar of mechanics. Eq. (25) was first developed by him in a work written in 1897.

is taken into account by the introduction in place of u of some effective velocity u_e greater than u (for instance, at $u = 1,900$ m/sec, $u_e = 2,200$ m/sec).

Let us develop the equation of motion of a rocket subjected to the thrust force alone, considering $F' = 0$ and the escape velocity u of the gases to be constant. If we direct the x axis in the direction of the motion (see Fig. 309), then $v_x = v$, $u_x = -u$, and, assuming $F' = 0$, Eq. (25) in terms of the projections on the x axis takes the form

$$M \frac{dv}{dt} = -u \frac{dM}{dt} \quad \text{or} \quad dv = -u \frac{dM}{M}.$$

Integrating and assuming that at the initial moment the mass $M = M_0$ and the velocity $v = v_0$ and is directed along Ox , we obtain

$$v = v_0 + u \ln \frac{M_0}{M}. \quad (28)$$

Let us denote the mass of the rocket with all its equipment (the payload) by M_r and the mass of the fuel M_f . Then, evidently, $M_0 = M_r + M_f$, and after the fuel is burned out the total mass of the rocket will be equal to M_r . Substituting these values into Eq. (28), we obtain *Tsiolkovsky's formula** for the velocity of a rocket when the fuel is completely burned out (the velocity at the end of the so-called *boost stage*):

$$v_1 = v_0 + u \ln \left(1 + \frac{M_f}{M_r} \right). \quad (29)$$

This result is strictly accurate for conditions of vacuum and absence of any force-field. It follows from Eq. (29) that the final velocity of a rocket depends on 1) its initial velocity v_0 ; 2) the relative velocity u of the exhaust gases; 3) the relative fuel stock M_f/M_r , known as *Tsiolkovsky's number*. It is very interesting to note that the velocity of a rocket at the end of the boost stage does not depend on the performance of the rocket motor, i.e., on the speed with which the fuel is burned. Table 1 offers an idea of the dependence of v_1/u on M_f/M_r (at $v_0 = 0$).

The practical importance of Tsiolkovsky's formula is that it points to the possible ways and means of developing the high velocities necessary for space flight. For this we must increase M_f/M_r , u , and v_0 , the more effective being the increase of u and v_0 . The

increase of u and M_t/M_r is connected with the type of fuel and the rocket design (for big liquid-propellant rockets $M_t/M_r = 3$ to 4 , $u = 2,000$ to $2,500$ m/sec). It is possible to increase v_0 by using a compound (multistage) rocket. As each stage burns out its fuel, it is separated automatically from the last stage, which thus receives an additional (initial) velocity.

Such multistage rockets were used for the Soviet sputnik and lunik launchings and the space flights of Yuri Gagarin and Herman Titov.

Chapter 26

THEOREM OF THE CHANGE IN THE ANGULAR MOMENTUM OF A SYSTEM

143. Total Angular Momentum of a System. The concept of the angular momentum, or moment of momentum, of a material particle was introduced in § 116. The total angular momentum of a system with respect to any centre O is defined as the quantity K_o equal to the geometrical sum of the angular momenta of all the particles of the system with respect to that centre: *

$$K_o = \sum m_o (m_k \mathbf{v}_k). \quad (30)$$

The angular momenta of a system with respect to each of three rectangular coordinate axes are found similarly:

$$\begin{aligned} K_x &= \sum m_x (m_k \mathbf{v}_k), & K_y &= \sum m_y (m_k \mathbf{v}_k), \\ K_z &= \sum m_z (m_k \mathbf{v}_k). \end{aligned} \quad (31)$$

By the theorem proved in § 43, K_x , K_y , K_z are the respective projections of vector K_o on the coordinate axes.

To understand the physical meaning of K , let us compute the angular momentum of a rotating body with respect to its axis of rotation. If a body rotates about a fixed axis Oz (Fig. 310), the linear velocity of any particle of the body at a distance h_k from the axis is ωh_k . Consequently, for that particle $m_z (m_k \mathbf{v}_k) = m_k \mathbf{v}_k h_k = m_k \omega h_k^2$. Then, taking the common multiplier ω outside of the parentheses, we obtain for the whole body

$$K_z = \sum m_z (m_k \mathbf{v}_k) = (\sum m_k h_k^2) \omega.$$

* We shall usually call the total angular momentum of a system just the angular momentum of that system.

Fig. 310.

The quantity in the parentheses is the moment of inertia of the body with respect to the z axis (§ 131). We finally obtain

$$K_z = J_z \omega. \quad (32)$$

Thus, the angular momentum of a rotating body with respect to the axis of rotation is equal to the product of the moment of inertia of the body and its angular velocity.

In the general case, vector K_o for a rotating body is not equal in magnitude to K_z or directed along axis Oz , since K_o has two more components, K_x and K_y , which are not zero. If, however, the axis of rotation coincides with a body's axis of symmetry, the momenta of symmetrically located points (see Fig. 310) will be equal in magnitude and oppositely directed, and the sums of the moments of these momenta with respect to the x and y axes will vanish ($K_x = K_y = 0$). Consequently, in this case vector K_o will be directed along the axis of rotation and will be equal in magnitude to K_z , i.e., to $J_z \omega$.

If a system consists of several bodies rotating about the same axis, then, apparently,

$$K_z = J_{1z} \omega_1 + J_{2z} \omega_2 + \dots + J_{nz} \omega_n. \quad (32')$$

The analogy between Eqs. (19) and (32) will be readily noticed: the momentum of a body is the product of its mass (the quantity characterising the body's inertia in translatory motion) and its velocity; the angular momentum of a body is equal to the product of its moment of inertia (the quantity characterising a body's inertia in rotational motion) and its angular velocity.

Just as the momentum of a system is a characteristic of its translatory motion (see § 138), the total angular momentum of a system is a characteristic of its rotational motion.

144. Theorem of the Change in the Total Angular Momentum of a System (the Principle of Moments). The principle of moments, which was proved for a single particle (§ 116), is valid for all the particles of a system. If, therefore, we consider a particle of mass m_k and velocity \mathbf{v}_k belonging to a system, we have for that particle

$$\frac{d}{dt} [m_o (m_k \mathbf{v}_k)] = m_o (\mathbf{F}_k^e) + m_o (\mathbf{F}_k^i),$$

where \mathbf{F}_k^e and \mathbf{F}_k^i are the resultants of all the external and internal forces acting on the particle.

Writing such equations for all the particles of the system and adding them, we obtain

$$\frac{d}{dt} [\sum m_o (m_k \mathbf{v}_k)] = \sum m_o (\mathbf{F}_k^e) + \sum m_o (\mathbf{F}_k^i).$$

But from the properties of the internal forces of a system (§ 129), the last summation vanishes. Hence, taking into account Eq. (30), we obtain finally

$$\frac{dK_o}{dt} = \sum m_o (F_k^e). \quad (33)$$

This equation states the following principle of moments for a system: *The derivative of the total angular momentum of a system about any fixed centre with respect to time is equal to the sum of the moments of all the external forces acting on that system about that centre.*

Projecting both sides of Eq. (33) on a set of fixed axes $Oxyz$ and taking into account the theorem proved in § 43, we obtain

$$\frac{dK_x}{dt} = \sum m_x (F_k^e), \quad \frac{dK_y}{dt} = \sum m_y (F_k^e), \quad \frac{dK_z}{dt} = \sum m_z (F_k^e). \quad (34)$$

Equations (34) express the principle of moments with respect to any fixed axis.

The following principle (which we present without proof) is important: *Eqs. (33) and (34) are also valid for a system of moving coordinate axes, but only if their origin coincides with the centre of mass of the system and is in translatory motion together with it.*

The theorem just proved is widely used in studying the rotation of a body about a fixed axis, and also in the theory of gyroscopic motion and the theory of impact. This, however, is not all. It was proved in the course of kinematics that the most general motion of a body is a combination of a translation together with some pole and a rotation about that pole. If the pole is located in the centre of mass, the translatory component of the motion can be investigated by applying the theorem of the motion of centre of mass, and the rotational component, by the theorem of moments. This indicates the theorem's importance in studying the motion of free bodies (a flying aircraft, shell or missile) and, in particular, in studying plane motion (§ 156).

The principle of moments is also convenient in investigating the rotation of a system, because, analogous to the theorem of the change in linear momentum, it makes it possible to exclude from consideration all immediately unknown internal forces.

145. The Law of Conservation of the Total Angular Momentum. The following important corollaries can be derived from the principle of moments.

1) Let the sum of the moments of all the external forces acting on a system with respect to a centre O be zero:

$$\sum m_o (F_k^e) = 0.$$

It follows, then, from Eq. (33) that $K_o = \text{const.}$ Thus, if the sum of the moments of all external forces acting on a system taken with respect to any centre is zero, the total angular momentum of the system with respect to that centre is constant in magnitude and direction. Application of this result for the case of planetary motion was considered in § 116.

2) Let the external forces acting on a system be such that the sum of their moments with respect to any fixed axis Oz is zero:

$$\sum m_z (F_k') = 0.$$

It follows, then, from Eqs. (34) that $K_z = \text{const.}$ Thus, if the sum of the moments of all the external forces acting on a system with respect to any axis is zero, the total angular momentum of the system with respect to that axis is constant.

These conclusions express the law of conservation of the total angular momentum of a system. It follows from them that internal forces cannot change the total angular momentum of a system.

Rotating Systems. Consider a system rotating about an axis Oz which is fixed or passes through the centre of mass. By Eq. (32), $K_z = J_z \omega$, and if $\sum m_z (F_k') = 0$, then

$$J_z \omega = \text{const.}$$

This leads us to the following conclusions:

a) If a system is *non-deformable* (a rigid body), then $J_z = \text{const.}$, whence $\omega = \text{const.}$ That is, a rigid body will rotate about a fixed axis with a constant angular velocity.

b) If a system is *deformable*, it will have particles which, under the action of internal (or external) forces, may move away from the axis, thereby increasing J_z , or approach the axis, thereby decreasing J_z . But as $J_z \omega = \text{const.}$, the angular velocity of the system will decrease as the moment of inertia increases, and increase as the moment of inertia decreases. Thus, the action of internal forces can change the angular velocity of a rotating system, as the constancy of K_z does not, in the general case, mean the constancy of ω .

Let us consider a few examples.

a) **Experiments with Zhukovsky's Platform.** The law of conservation of angular momentum can be demonstrated visually by means of a simple instrument known as "Zhukovsky's platform." It represents a circular horizontal disc supported by step ball bearings so that it is free to rotate with negligible friction about a vertical axis z . For a person standing on the platform, $\sum m_z (F_k') = 0$, and consequently, $J_z \omega = \text{const.}$ If, now, the

person stretches out his arms and twists himself to start rotating about the vertical axis and then lowers his arms, J_z will decrease and, consequently, the angular velocity will increase. This trick of increasing angular velocity is widely employed by ballet dancers, in turning somersaults, etc.

A person standing motionless on the platform ($K_z = 0$) can turn in any direction by merely extending one arm horizontally and sweeping it in the opposite direction. His angular velocity will be such that the total quantity K_z for the system will remain zero.

b) *Riding a Swing*. When a person rides a swing, the pressure of his feet (an internal force) cannot by itself make him swing higher. For this, in the upper left-hand position A_0 of the swing, the person must squat down. When the swing passes through the vertical, he stands up quickly. This brings the mass closer to the axis of rotation z , the quantity J_z decreases, and the angular velocity ω jumps. The increase in ω will carry the swing higher than the initial height A_0 . In the upper right-hand position, when $\omega = 0$, the person again squats (which, evidently, will not influence the value of ω), and passing through the vertical he stands up again, etc. As a result the amplitude of the swing will increase with each swing.

The forced vibration of the swing is called *parametric*, as it is induced not by a periodically alternating force (§ 126) but as a result of a change in the parameters of the system: its moment of inertia and the position of its centre of gravity.

c) *Rotation of a Gun Shell in the Barrel*. If we consider a gun barrel and a shell in it as a single system, the pressure of the gases when the gun is fired will be an internal force which cannot change the angular momentum of the system, which was zero before the shot. Therefore, if the grooves in the bore make the shell rotate, say, to the right, the barrel will tend to rotate to the left so that at any instant $J_{\text{shell}} \omega_{\text{shell}} = J_{\text{barrel}} \omega_{\text{barrel}}$. This rotation is opposed by the trunnions of the gun carriage, and an additional force is brought to act on them.

d) *Reaction Moment of a Propeller*. The rotor of a helicopter not only drives the air downwards (see § 140, example b), but also imparts a rotation to the mass being swept down. The total angular momentum of the mass of the driven air and the helicopter must be zero, as initially the system was motionless and the forces of interaction between the rotor and the air are internal. Therefore, the helicopter will start rotating in the opposite direction of the rotor. The turning moment acting on the helicopter is called the *reaction moment*, or *reaction torque*.

In order to prevent the reaction rotation of a single-rotor helicopter, it is provided with an auxiliary torque-control rotor

mounted on the tail boom. In a multiple-rotor helicopter the rotors are made to revolve in opposite directions.

The reaction moment can be used for the experimental determination of the torque developed by an aircraft engine, since the two quantities are equal in magnitude and the reaction moment can be measured by mounting the engine on a suitable balance.

146. Solution of Problems. The principle of moments is convenient in studying the rotation of bodies (§ 153) or the motion of systems including rotating and translating bodies (Problem 133).

The law of conservation of angular momentum makes it possible to determine the change of the angular velocity (or the angle of rotation) of any part of a system if the displacement or the velocity of the other portion of the system is known. In solving such problems, all immediately unknown internal forces and external forces intersecting with, or parallel to, the axis of rotation can be ignored.

Problem 130. Two discs having moments of inertia J_1 and J_2 are mounted on a shaft as shown in Fig. 311. If the shaft is twisted and then released, find the dependence between the angular velocities and the angle of turn of the discs in the ensuing torsional vibrations. Neglect the mass of the shaft.

Solution. To exclude the unknown elastic forces which cause the discs to vibrate, consider both discs and the shaft as a single system. The external forces (the reactions of the bearings and the force of gravity) intersect with axis x , whence $\sum m_x(F_k^e) = 0$, and $K_x = \text{const.}$ But since at the initial moment $K_x = 0$, during the whole of the vibration we must have $K_x = J_1\omega_1 + J_2\omega_2 = 0$ (the angular momentum of the system with respect to the x axis equals the sum of the angular momenta of each disc with respect to the same axis). We find from this that

$$\omega_1 = -\frac{J_2}{J_1}\omega_2 \quad \text{and} \quad \varphi_1 = -\frac{J_2}{J_1}\varphi_2,$$

where φ_1 and φ_2 are the angles through which the discs were twisted, measured from the initial position (the latter result is obtained by integrating the first equation).

Thus, the vibrations will be in opposite directions, and the angular amplitudes will be inversely proportional to the moments of inertia of the discs. The stationary, or nodal, cross section of the shaft lies closer to the disc whose moment of inertia is larger.

Problem 131. A governor AB with a moment of inertia J_2 consists of two symmetrically placed weights of mass m , each attached to two springs as shown in Fig. 312, and it rotates about a vertical axis Oz . At time $t_0 = 0$, the governor receives an angular velocity ω_0 , and each weight starts to oscillate in damped vibration about its respective centre C at a distance l from axis Oz . Neglecting friction and considering the weights as particles, determine the dependence of the angular velocity ω of the governor on the position of the weights.

Fig. 311.

Solution. To exclude the unknown elastic forces of the springs, consider the governor and the weights as one system. Then $\sum m_z (F_k^e) = 0$, and $K_z = \text{const.}$ At time $t_0 = 0$, the displacement $x = 0$ and $K_{z0} = (J_z + 2ml^2) \omega_0$. At any arbitrary instant t , $K_z = [J_z + 2m(l+x)^2] \omega$. As $K_z = K_{z0}$,

$$\omega = \frac{J_z + 2ml^2}{J_z + 2m(l+x)^2} \omega_0.$$

Consequently, when $x > 0$, $\omega < \omega_0$, and when $x < 0$, $\omega > \omega_0$, i.e., the angular velocity changes about a mean value ω_0 . When the vibrations of the weights dampen with time, x tends to zero, and ω to ω_0 .

Fig. 312.

Fig. 313.

Problem 132. A track is laid along the circumference of a disc of radius R and weight P . Standing on the track is a toy spring-wound car of weight p . The disc rotates together with the car about a vertical axis Oz with an angular velocity ω_0 (Fig. 313). Determine how the angular velocity of the disc will change if at some instant the car will start moving in the direction of the rotation with a velocity u relative to the disc.

Solution. To exclude the unknown frictional forces between the wheels of the car and the disc, consider both as one system. The moments of the external forces acting on the system with respect to the z axis are zero. Consequently, $K_z = \text{const.}$ Considering the disc to be homogeneous ($J_z = 0.5MR^2$) and the car as a particle, we have

$$K_{z0} = \left(0.5 \frac{P}{g} R^2 + \frac{p}{g} R^2 \right) \omega_0.$$

When the car starts moving its absolute velocity will be $v_a = u + \omega R$, where ω is the new angular velocity of the disc. The angular momentum of the car about the z axis will be $mv_a R = m(uR + \omega R^2)$, and for the whole system we have

$$K_{z1} = 0.5 \frac{P}{g} R^2 \omega + \frac{p}{g} (uR + R^2 \omega).$$

As $K_z = \text{const.}$, $K_{z1} = K_{z0}$, whence $\omega = \omega_0 - \frac{P}{0.5P + p} \frac{u}{R}$.

The angular velocity of the disc, we see, decreases. If the car travels in the opposite direction, ω will increase.

Note that in calculating K_z the *absolute velocities* of all moving points of the system were taken.

Problem 133. Wound on a drum of weight P and radius r (Fig. 314) is a string carrying a load A of weight Q . Neglecting the mass of the string and

iriction, determine the angular acceleration of the drum when the load falls, if the radius of gyration of the drum with respect to its axis is ρ .

Solution. Applying the theorem of moments with respect to axis O , we have

$$\frac{dK_o}{dt} = \sum m_o (F_k^e). \quad (a)$$

The moving system consists of two bodies, consequently

$$K_o = K_{\text{drum}} + K_{\text{load}}.$$

The load is in translatory motion, and we consider it as a particle. Its velocity is $v = \omega r$. The drum rotates about a fixed axis, consequently,

$$K_{\text{load}} = \frac{Q}{g} v^2 = \frac{Q}{g} r^2 \omega^2; \quad K_{\text{drum}} = J_o \omega^2 = \frac{P}{g} \rho^2 \omega^2,$$

and

$$K_o = (Qr^2 + P\rho^2) \frac{\omega^2}{g}.$$

Fig. 314.

Substituting this expression for K_o into equation (a), we obtain

$$\frac{Qr^2 + P\rho^2}{g} \frac{d\omega}{dt} = Qr,$$

whence

$$\epsilon = \frac{Qrg}{Qr^2 + P\rho^2}.$$

Chapter 27

THEOREM OF THE CHANGE IN THE KINETIC ENERGY OF A SYSTEM

147. Kinetic Energy of a System The kinetic energy of a system is defined as a scalar quantity T equal to the arithmetical sum of the kinetic energies of all the particles of the system:

$$T = \sum \frac{m_k v_k^2}{2}. \quad (35)$$

Kinetic energy is a characteristic of both the translatory and rotational motion of a system, which is why the theorem of the change in kinetic energy is so frequently used in problem solutions. The main difference between T and the previously introduced characteristics Q and K_o is that kinetic energy is a scalar quantity, and essentially a positive one. It, therefore, does not depend on the directions of the absolute motions of parts of a system and does not characterise the changes in these directions.

Another important point should be noted. Internal forces act on the parts of a system in mutually opposite directions. For this

reason, as we have seen, they do not change the vector parameters \mathbf{Q} and \mathbf{K}_0 . But if, under the action of internal forces, the speeds of the particles of a system change, the quantity T will change too. Consequently, the kinetic energy of a system differs further from the quantities \mathbf{Q} and \mathbf{K}_0 in that it is affected by the action of both external and internal forces.

If a system consists of several bodies, its kinetic energy is, evidently, equal to the sum of the kinetic energies of all the bodies:

$$T = \sum T_k.$$

Let us develop the equations for computing the kinetic energy of a body in different types of motion.

1. **Translatory Motion.** In this case all the points of a body have the same velocity, which is equal to the velocity of the centre of mass. Therefore, for any point $v_k = v_C$, and Eq. (35) gives

$$T_{\text{trans}} = \sum \frac{m_k v_C^2}{2} = \frac{1}{2} \left(\sum m_k \right) v_C^2,$$

or

$$T_{\text{trans}} = \frac{1}{2} M v_C^2. \quad (36)$$

Thus, in translatory motion, the kinetic energy of a body is equal to half the product of the body's mass and the square of the velocity of the centre of mass. The value of T does not depend on the direction of motion.

2. **Rotational Motion** The velocity of any point of a body rotating about an axis Oz (see Fig. 310) is $v_k = \omega h_k$, where h_k is the distance of the point from the axis of rotation, and ω is the angular velocity of the body. Substituting this expression into Eq. (35) and taking the common multipliers outside the parentheses, we obtain

$$T_{\text{rotation}} = \sum \frac{m_k \omega^2 h_k^2}{2} = \frac{1}{2} \left(\sum m_k h_k^2 \right) \omega^2.$$

The term in the parentheses is the moment of inertia of the body with respect to the axis z . Thus we finally obtain

$$T_{\text{rotation}} = \frac{1}{2} J_z \omega^2, \quad (37)$$

i.e., in rotational motion, the kinetic energy of a body is equal to half the product of the body's moment of inertia with respect to the axis of rotation and the square of its angular velocity. The value of T does not depend on the direction of the rotation.

3. **Plane Motion***. In plane motion, the velocities of all the points of a body are at any instant directed as if the body were rotating about an axis perpendicular to the plane of motion and passing through the instantaneous centre of zero velocity P (Fig. 315). Hence, by Eq. (37)

$$T_{\text{plane}} = \frac{1}{2} J_P \omega^2, \quad (37')$$

where J_P is the moment of inertia of the body with respect to the instantaneous axis of rotation, and ω is the angular velocity of the body.

The quantity J_P in Eq. (37') is variable, as the position of the centre P continuously changes with the motion of the body. Let us introduce instead of J_P a constant moment of inertia J_C with respect to an axis through the centre of mass C of the body. By the parallel-axis theorem, (§ 133), $J_P = J_C + Md^2$, where $d = PC$. Substituting this expression for J_P into Eq. (37') and taking into account that point P is the instantaneous centre of zero velocity and therefore $\omega d = \omega PC = v_C$, where v_C is the velocity of the centre of mass, we obtain finally

$$T_{\text{plane}} = \frac{1}{2} M v_C^2 + \frac{1}{2} J_C \omega^2. \quad (38)$$

Thus, in plane motion, the kinetic energy of a body is equal to the kinetic energy of translation of the centre of mass plus the kinetic energy of rotation relative to the centre of mass.

4. **The Most General Motion of a Body**. Taking the centre of mass C as the pole (Fig. 316), the most general motion of a body is a combination of a translation with the velocity v_C of the pole and a rotation about the instantaneous axis CC' through the pole (see § 88). Then, as shown in the course of kinematics, the velocity v_k of any point of the body is equal to the geometrical sum of the velocity v_C of the pole and the velocity v'_k of the point in its rotation with the body about axis CC' :

$$v_k = v_C + v'_k.$$

* This case can be developed as a particular case of the most general motion of a rigid body discussed in the following item.

Fig. 315.

Fig. 316.

In magnitude $v'_k = \omega h_k$, where h_k is the distance of the point from axis CC' and ω is the *absolute* angular velocity of the body about that axis. It follows from this that*

$$v_k^2 = \mathbf{v}_k^2 = (\mathbf{v}_C + \mathbf{v}'_k)^2 = v_C^2 + v_k'^2 + 2\mathbf{v}_C \cdot \mathbf{v}'_k.$$

Substituting this expression into Eq. (35) and taking into account that $v'_k = \omega h_k$, we find

$$T = \frac{1}{2} \left(\sum m_k \right) v_C^2 + \frac{1}{2} \left(\sum m_k h_k^2 \right) \omega^2 + \mathbf{v}_C \cdot \sum m_k \mathbf{v}'_k,$$

where the common multipliers have been taken outside the parentheses.

In this equation the term in the first parentheses gives the mass M of the body, and the term in the second parentheses gives the moment of inertia $J_{CC'}$ of the body with respect to the instantaneous axis CC' . In the last term $\sum m_k \mathbf{v}'_k = 0$ as it represents the linear momentum of the body in its rotation about axis CC' , which passes through the centre of mass (see § 138).

Therefore we finally have

$$T = \frac{1}{2} M v_C^2 + \frac{1}{2} J_{CC'} \omega^2. \quad (38')$$

Thus, *in the most general motion of a body, the kinetic energy is equal to the kinetic energy of translation of the centre of mass of the body plus the kinetic energy of rotation about an axis through the centre of mass.*

If the pole is not taken in the centre of mass, but in another point A , such that axis AA' does not pass through the centre of mass, then for this axis $\sum m_k \mathbf{v}'_k \neq 0$, and we cannot develop an equation of the form (38') (see Problem 136).

In computing kinetic energy, it is important to remember that all the equations contain the *absolute* velocities of the respective particles or bodies. Characteristic mistakes are pointed out in Problems 135 and 136.

Problem 134. Find the kinetic energy of a uniform cylindrical wheel of mass M rolling without slipping, if the velocity of its centre is v_C (Fig. 317).

* In vector analysis there exists the concept of the scalar, or dot, product of two vectors \mathbf{u} and \mathbf{v} , which is equal to the product of their magnitudes and the cosine of the angle α between them: $\mathbf{u} \cdot \mathbf{v} = uv \cos \alpha$. It follows, then, that $\mathbf{v}^2 = \mathbf{v} \cdot \mathbf{v} = vv \cos 0^\circ = v^2$, i.e., the scalar square of a vector is equal to the square of its magnitude. This result has been employed here.

Solution. The wheel is in plane motion. By Eq. (38),

$$T = \frac{1}{2} M v_C^2 + \frac{1}{2} J_C \omega^2.$$

As the body is a uniform cylinder, we have (see § 132) $J_C = 0.5 MR^2$, where R is the radius of the wheel. On the other hand, since point B is the instantaneous centre of zero velocity of the wheel,

$v_C = \omega BC = \omega R$, whence $\omega = v_C / R$.

Substituting these expressions into the equation, we find

$$T = \frac{1}{2} M v_C^2 + \frac{1}{4} M R^2 \frac{v_C^2}{R^2} = \frac{3}{4} M v_C^2.$$

Fig. 317.

Problem 135. When body A in Fig. 318 translates with a velocity u , body B moves in the slots of body A with a velocity v . If angle α is known, determine the kinetic energy of body B .

Solution. The absolute motion of body B is a translation with a velocity $v_a = u + v$ (see § 94). Then

$$T = \frac{1}{2} M v_a^2 = \frac{1}{2} M (u^2 + v^2 + 2uv \cos \alpha).$$

A characteristic mistake in problems of this type is to regard the kinetic energy of the body as the sum of the energies of the relative and transport motions:

$$T = T_{\text{rel}} + T_{\text{tr}} = \frac{1}{2} M v^2 + \frac{1}{2} M u^2,$$

and thus, it will be noticed, the component $Muv \cos \alpha$ drops out of the solution.

Fig. 318.

Fig. 319.

Thus, in the most general case of relative motion, the total kinetic energy of a body does not equal the sum of the kinetic energies of its relative and transport motions.

Problem 136. A mechanism consists of a part which is translated with a velocity u , and a rod AB of length l and mass M hinged at A (Fig. 319). The rod rotates about axis A with an angular velocity ω . Determine the kinetic energy of the rod if angle α is given.

Solution. The rod performs plane motion, and by Eq. (38)

$$T = \frac{1}{2} M v_C^2 + \frac{1}{2} J_C \omega^2.$$

The velocity of point C is compounded of the velocities u and v_{rel} , where in magnitude $v_{\text{rel}} = \omega \frac{l}{2}$. Consequently (see Fig. 319), $v_C^2 = u^2 + v_{\text{rel}}^2 + 2uv_{\text{rel}} \cos \alpha$.

The angular velocity of the rod about C is the same as about A , as ω does not depend on the location of the pole (see § 77). Furthermore, it was shown in Problem 122 (§ 133) that $J_C = \frac{1}{12} Ml^2$,

Substituting all these expressions, we obtain

$$T = \frac{1}{2} M \left(u^2 + \omega^2 \frac{l^2}{4} + u\omega l \cos \alpha \right) + \frac{1}{24} Ml^2 \omega^2 = \frac{1}{2} Mu^2 + \frac{1}{6} Ml^2 \omega^2 + \frac{1}{2} Ml\omega u \cos \alpha.$$

A common mistake in this type of problem is to assume that

$$T = T_{\text{trans}} + T_{\text{rotation}} = \frac{1}{2} Mu^2 + \frac{1}{2} J_A \omega^2 = \frac{1}{2} Mu^2 + \frac{1}{6} Ml^2 \omega^2.$$

This is wrong because, as previously shown, the formula $T = T_{\text{trans}} + T_{\text{rotation}}$ is valid only when the axis of rotation passes through the centre of mass, which is not the case in this problem.

148. Theorem of the Change in the Kinetic Energy of a System. The theorem proved in § 114 is valid for any point of a system. Therefore, if we take any particle of mass m_k and velocity v_k belonging to a system, we have for this particle

$$\frac{m_k v_{k1}^2}{2} - \frac{m_k v_{k0}^2}{2} = A_k^e + A_k^i,$$

where v_{k0} and v_{k1} denote the particle's velocity at the beginning and the end of the displacement, and A_k^e and A_k^i are the sums of the work done by all the external and internal forces acting on the particle through this displacement.

If we write similar equations for all the particles of a system and add them up, we obtain

$$\sum \frac{m_k v_{k1}^2}{2} - \sum \frac{m_k v_{k0}^2}{2} = \sum A_k^e + \sum A_k^i,$$

or

$$T_1 - T_0 = \sum A_k^e + \sum A_k^i, \quad (39)$$

where T_0 and T_1 denote the kinetic energy of the system at the beginning and the end of the displacement.

This equation states the following theorem of the change in kinetic energy: *The change in the kinetic energy of a system during any displacement is equal to the sum of the work done by all the external and internal forces acting on the system in that displacement.*

For an infinitesimal displacement of a system the theorem takes the form

$$dT = dA^e + dA^i, \quad (40)$$

where dA^e and dA^i denote the elemental work done by all the external and internal forces acting on the system.

Unlike the previously proved theorems, in Eqs. (39) and (40) the internal forces are not ignored. For, if F_{12}^i and F_{21}^i are the forces of interaction between points B_1 and B_2 of a system (see Fig. 320), then $F_{12}^i + F_{21}^i = 0$, but at the same time point B_1 may be moving towards B_2 , and point B_2 towards B_1 . The work done by each force is positive, and the total work will not be zero. An example is the phenomenon of recoil (Problem 128, Fig. 307). The internal forces (the pressure of the gases) acting on the shell and the recoiling parts do a positive work. The sum of this work is not zero, and it changes the kinetic energy of the system from $T_0 = 0$ at the beginning of the shot to $T_1 = T_{\text{projectile}} + T_{\text{recoil}}$ at the end of the shot.

Fig. 320.

The Case of Non-Deformable Systems. A non-deformable system is defined as one in which the distance between the points of application of the internal forces does not change during the motion of the system. Special cases of such systems are a rigid body and an inextensible string.

Let two points B_1 and B_2 of a non-deformable system (Fig. 320) be acting on each other with forces F_{12}^i and F_{21}^i ($F_{21}^i = -F_{12}^i$) and let their velocities at some instant be v_1 and v_2 . Their displacements in a time interval dt will be $ds_1 = v_1 dt$ and $ds_2 = v_2 dt$ directed along vectors v_1 and v_2 . But as line B_1B_2 is non-deformable, it follows from the laws of kinematics that the projections of vectors v_1 and v_2 , and consequently of the displacements ds_1 and ds_2 , on the direction of B_1B_2 will be equal, i.e., $B_1B'_1 = B_2B'_2$. Then the elemental work done by forces F_{12}^i and F_{21}^i will be equal in magnitude and opposite in sense, and their sum will be zero. This holds for all internal forces in any displacement of a system.

We conclude from this that *the sum of the work done by all the internal forces of a non-deformable system is zero*, and Eq. (39) takes the form

$$T_1 - T_0 = \sum A_k^e. \quad (41)$$

Both the external and internal forces in Eqs. (39)-(41) include the reactions of constraints. If the constraints on which the bodies of a system move are smooth, then as shown in § 114, the work

done by the reactions of these constraints in any displacement of the system is zero and the reactions will not enter into Eqs. (39)-(41).

Thus, in applying the theorem of the change in kinetic energy to frictionless systems, all the immediately unknown reactions of the constraints will be excluded from the problem. This is where its practical value lies.

Note that all the foregoing theorems made it possible to exclude the internal forces from the equations of motion, but all the external forces, including the immediately unknown reactions of the external constraints, entered into the equations.

149. Some Cases of Computation of Work. Work done by forces is computed from the equations developed in §§ 112 and 113. Let us consider several more cases.

1) **Work Done by Gravitational Forces Acting on a System.** The work done by a gravitational force acting on a particle of weight p_k will be $p_k(z_{k0} - z_{k1})$ where z_{k0} and z_{k1} are the coordinates of the initial and final positions of the particle (see § 113). Then the total work done by all the gravitational forces acting on a system will be, by Eqs. (74) in § 53,

$$A = \sum p_k z_{k0} - \sum p_k z_{k1} = \\ = P(z_{C0} - z_{C1}) = \pm Ph_C,$$

where P is the weight of the system, and h_C is the vertical displacement of the centre of gravity (or centre of mass) of the system. Thus, the work done by the gravitational forces

acting on a system is computed as the work done by their resultant P in the displacement of the centre of gravity (or the centre of mass) of the system.

2) **Work Done by Forces Applied to a Rotating Body.** The elemental work done by the force F applied to the body in Fig. 321 will be (see § 112)

$$dA = F_\tau ds = F_\tau h d\varphi,$$

since $ds = h d\varphi$, where $d\varphi$ is the angle of rotation of the body.

But it is evident that $F_\tau h = m_z(F)$. We shall call the quantity $M_z = m_z(F)$ the *turning moment*, or *torque*. Thus we obtain

$$dA = M_z d\varphi. \quad (42)$$

i.e., the elemental work, in this case, is equal to the product of

Fig. 321.

the torque and the elemental angle of rotation. Eq. (42) is valid when several forces are acting, if it is assumed that $M_z = \sum m_z(F_k)$.

The work done in a turn through a finite angle φ will be

$$A = \int_0^{\varphi_1} M_z d\varphi, \quad (43)$$

and, for a constant torque ($M_z = \text{const.}$),

$$A = M_z \varphi_1. \quad (44)$$

If acting on a body is a force couple lying in a plane normal to Oz , then, evidently, M_z in Eqs. (42)-(44) will denote the moment of that couple.

Let us see how power is determined in this case (see § 112). From Eq. (42) we find

$$W = \frac{dA}{dt} = \frac{M_z d\varphi}{dt} = M_z \omega.$$

Thus, the power developed by forces acting on a rotating body is equal to the product of the torque and the angular velocity of the body. For the same power, the torque increases as the angular velocity decreases.

3) Work Done by Frictional Forces Acting on a Rolling Body. A wheel of radius R (Fig. 322) rolling without slipping on a plane (surface) is subjected to the action of a frictional force F_{fr} , which prevents the slipping of the point of contact B on the surface. The elemental work done by this force is $dA = -F_{fr} ds_B$. But point B is the instantaneous centre of velocity (§ 81), and $v_B = 0$. As $ds_B = v_B dt$, $ds_B = 0$, and for every elemental displacement $dA = 0$.

Fig. 322.

Thus, in rolling without slipping, the work done by the frictional force preventing slipping is zero in any displacement of the body. For the same reason, the work done by the normal reaction N is also zero.

The resistance to rolling is created by the couple (N, P) of moment $M = kN$, where k is the coefficient of rolling friction (see § 40). Then by Eq. (42), and taking into account that the angle of rotation of a rolling wheel is $d\varphi = \frac{ds_C}{R}$, we obtain

$$dA_{\text{roll}} = -kN d\varphi = -\frac{k}{R} N ds_C, \quad (45)$$

where ds_C is the elemental displacement of the centre C of the wheel.

If $N = \text{const.}$, then the total work done by the forces resisting rolling will be

$$A_{\text{roll}} = -kN\varphi_1 = -\frac{k}{R} N s_C. \quad (45')$$

As the quantity k/R is small, rolling friction can, in the first approximation, be neglected as compared with other resisting forces.

150. Solution of Problems. The theorem of the change in kinetic energy is useful when a moving system is non-deformable. In this case the theorem makes it possible to exclude from consideration all immediately unknown internal forces and, if there is no friction, also all the immediately unknown reactions of external constraints.

In the case of a deformable system, the theorem gives a solution only if the internal forces are known. If they are not known (Problems 124, 128, etc.) the energy theorem is insufficient to obtain a solution.

Eq. (41) is convenient in solving problems where the given and required quantities include: 1) the acting forces, 2) *the displacement of the system*, 3) the velocities of the bodies (linear or angular) at the beginning and the end of the displacement. The acting forces must be constant or dependent only on the displacement (distance).

It is also very important to bear in mind that the kinetic energy theorem can be used to develop the *differential equations of motion of a system* and, in particular, to find the accelerations of moving bodies. For this write Eq. (41), differentiate both sides with respect to time, and eliminate the velocity (see Problems 139 and 140). For arbitrarily acting forces the equations are more conveniently written in the form (40), i.e., in differential form (see Problems 141 and 148).

Fig. 323.

Problem 137. A rod AB of length l is hinged as shown at point A (Fig. 323). Neglecting friction, determine the minimum velocity ω_0 that must be

imparted to the rod so that it would swing into a horizontal configuration.

Solution. The given and required quantities include ω_0 , $\omega_1 = 0$, and *the displacement* of the system as defined by angle B_0AB_1 . Therefore, the problem is best solved by applying Eq. (41):

$$T_1 - T_0 = \sum A_k^e. \quad (a)$$

Denoting the weight of the rod by P , compute all the quantities in the equation. From Eqs. (37) and (9) we find

$$T_0 = \frac{1}{2} J_A \omega_0^2 = \frac{1}{6} \frac{P}{g} l^2 \omega_0^2.$$

Since in the final configuration the velocity of the rod is zero, $T_1 = 0$. The work is done only by force P , and $A^e = -Ph_C = -P \frac{l}{2}$. Substituting these values into equation (a), we obtain

$$-\frac{1}{6} \frac{P}{g} l^2 \omega_0^2 = -P \frac{l}{2},$$

whence

$$\omega_0 = \sqrt{\frac{3g}{l}}.$$

Problem 138. Two pulleys A and B are connected by a belt (Fig. 324). When the motor is switched off, pulley A of radius R , has an angular velocity ω_0 . The total weight of the pulleys is P , and of the belt p . A brake

Fig. 324.

shoe is applied to pulley A with a force Q to stop the rotation; the coefficient of friction of the shoe on the pulley is f . Neglecting friction in the axes and considering the pulleys to be homogeneous discs, determine how many revolutions pulley A will make before stopping.

Solution. We shall use Eq. (41) to determine the required number of revolutions N :

$$T_1 - T_0 = \sum A_k^e. \quad (a)$$

In computing kinetic energy, it should always be remembered that the kinetic energy of a system equals the sum of the kinetic energies of all the component bodies. From the conditions of the problem, $T_1 = 0$, and $T_0 = T_A + T_B + T_p$. Taking into account that the initial velocities of all the points of the belt $v_{b0} = \omega_0 R = \omega'_0 r$, where ω'_0 and r are the initial angular velocity and the radius of pulley B , we find from Eqs. (37) and (11):

$$T_A = \frac{1}{2} \left(\frac{P_A}{2g} R^2 \right) \omega_0^2, \quad T_B = \frac{1}{2} \left(\frac{P_B}{2g} r^2 \right) \omega_0'^2 = \frac{1}{4} \frac{P_B}{g} R^2 \omega_0^2,$$

$$T_p = \frac{1}{2} \frac{P}{g} v_{b0}^2 = \frac{1}{2} \frac{P}{g} R^2 \omega_0^2.$$

The last equation follows from the fact that all the points of the belt move with the same speed. Finally, as $P_A + P_B = P$, we obtain

$$T_0 = \frac{P + 2p}{4g} R^2 \omega_0^2.$$

Now compute the work done by the forces. In this case, the work done by gravity is zero, as the centres of gravity of the pulleys and the belt do not

change their position during the motion. The force of friction $F_{fr} = fQ$, and the work done by it is found from Eq. (44):

$$A_{fr} = - (fQR) \cdot \varphi_1 = - fQR \cdot 2\pi N.$$

Substituting all the found values into equation (a), we obtain finally

$$N = \frac{(P + 2p) R \omega_0^2}{8\pi g f Q}.$$

Problem 139. A cart is drawn with a constant force $Q = 16$ kg up an inclined plane making an angle $\alpha = 30^\circ$ with the horizontal (Fig. 325). The platform of the cart weighs $P = 18$ kg, and each of its uniform wheels weighs $p = 2$ kg. Determine: 1) the linear velocity v_1 of the cart, when it has travelled a distance $l = 4$ m, if $v_0 = 0$; 2) the acceleration of the cart. The wheels roll without slipping. Neglect the rolling friction.

Fig. 325.

Solution. 1) Let us use Eq. (41) to determine v_1 :

$$T_1 - T_0 = \sum A_k^e. \quad (a)$$

In our case $T_0 = 0$ and $T_1 = T_{\text{platform}} + 4T_{\text{wheel}}$. The cart is in translatory motion, and the kinetic energy of a uniform rolling wheel was calculated in Problem 134. Thus,

$$T_1 = \frac{1}{2} \frac{P}{g} v_1^2 + 4 \left(\frac{3}{4} \frac{p}{g} v_1^2 \right) = \frac{1}{2g} (P + 6p) v_1^2.$$

Work is done by force Q and the force of gravity $P_1 = (P + 4p)$. The work done by the frictional forces preventing slippage and by the normal reactions is zero (§ 149). Making the necessary computations, we find

$$A(Q) = Ql; \quad A(P_1) = - (P + 4p) h_C = - (P + 4p) l \sin \alpha.$$

Substituting these expressions into equation (a), we obtain

$$\frac{1}{2g} (P + 6p) v_1^2 = [Q - (P + 4p) \sin \alpha] l, \quad (b)$$

whence

$$v_1 = \sqrt{\frac{2gl [Q - (P + 4p) \sin \alpha]}{P + 6p}} = 2.8 \text{ m/sec.}$$

2) To determine the acceleration ω , let us consider the quantities v_1 and l in equation (b) as variables. Then, differentiating through with respect to time, we have

$$\frac{1}{g} (P + 6p) v \frac{dv}{dt} = [Q - (P + 4p) \sin \alpha] \frac{dl}{dt}.$$

But $\frac{dl}{dt} = v$, and $\frac{dv}{dt} = \omega$, and, eliminating v , we have

$$\omega = \frac{Q - (P + 4p) \sin \alpha}{P + 6p} g = 0.98 \text{ m/sec}^2.$$

Note the use of the theorem of the change in kinetic energy to determine the acceleration.

Problem 140. One end of a string passing over a pulley O (Fig. 326) is wound on a cylinder of radius R and weight P ; attached to the other end is a load D of weight Q . If $v_{C0} = 0$, determine the velocity v_C of the centre C of the cylinder after it has travelled a distance s , and the acceleration w_C of the centre. The coefficient of rolling friction of the cylinder is k , the radius of gyration of the cylinder with respect to its axis is ϱ . Neglect the mass of the string and the pulley.

Solution. 1) We use Eq. (41) to determine the velocity v_C :

$$T - T_0 = \sum A_k^e. \quad (a)$$

In our case $T_0 = 0$ and $T = T_{\text{cyl}} + T_D$. From Eqs. (36), (38), and (7),

$$\begin{aligned} T_D &= \frac{1}{2} \frac{Q}{g} v_D^2, \quad T_{\text{cyl}} = \\ &= \frac{1}{2} \frac{P}{g} v_C^2 + \frac{1}{2} \left(\frac{P}{g} \varrho^2 \right) \omega^2. \end{aligned}$$

Fig. 326.

As point B is the instantaneous centre of zero velocity, $\omega = \frac{v_C}{R}$, and $v_D = v_A = 2v_C$. Consequently,

$$T = \frac{1}{2g} \left[4Q + P \left(1 + \frac{\varrho^2}{R^2} \right) \right] v_C^2.$$

The forces doing work are Q and the couple (N, P) . As $v_D = 2v_C$, the displacement of load D is $h = 2s$, and $A(Q) = Q \cdot 2s$. The work done by the forces opposing the rolling can be found from Eq. (45'), as $N = P = \text{const}$. Then,

$$\sum A_k^e = 2Qs - \frac{k}{R} Ps.$$

Substituting the found expressions into equation (a), we obtain

$$\frac{1}{2g} \left[4Q + P \left(1 + \frac{\varrho^2}{R^2} \right) \right] v_C^2 = \left(2Q - \frac{k}{R} P \right) s, \quad (b)$$

whence

$$v_C = \sqrt{\frac{2g(2QR - kP)Rs}{4QR^2 + P(R^2 + \varrho^2)}}.$$

2) As in the preceding problem, to determine w_C differentiate both sides of equation (b) with respect to time. Taking into account that $\frac{ds}{dt} = v_C$, we finally obtain

$$w_C = \frac{(2QR - kP)R}{4QR^2 + P(R^2 + \varrho^2)} g.$$

Problem 141. Referring to Fig. 327, a spiral spring is attached to gear 1 of radius r and weight P and to crank OC of length l and weight Q on which the gear is mounted. Gear 1 rolls on a fixed gear 2 of radius $R = l - r$. The moment of the spring $M_{sp} = \alpha$, where α is the angle of rotation of gear 1

with respect to the crank. Neglecting friction, determine the period of vibration of the crank if it is disturbed from its position of equilibrium. The mechanism works in a horizontal plane.

Solution. We shall define the position of the crank by the angle φ measured from its equilibrium position. To exclude the unknown reaction of axis C from the computation, consider gear 1 and the crank as a single system and develop the differential equation of its motion from Eq. (40).

First compute the kinetic energy T of the system in terms of the angular velocity ω_{cr} of the crank (as we are developing the law of motion of the crank). We have:

$$T = T_{cr} + T_{gear} = \frac{1}{2} J_{Ocr} \omega_{cr}^2 + \frac{1}{2} \frac{P}{g} v_C^2 + \frac{1}{2} J_{Cgear} \omega_{gear}^2, \quad (a)$$

Considering the crank as a homogeneous rod and the gear as a uniform disc, and taking into account that the point of contact is the instantaneous centre of zero velocity of gear 1, we have

$$J_{Ocr} = \frac{1}{3} \frac{Q}{g} l^2, \quad J_{Cgear} = \frac{1}{2} \frac{P}{g} r^2,$$

$$v_C = \omega_{cr} l, \quad \omega_{gear} = \frac{v_C}{r} = \frac{l}{r} \omega_{cr}.$$

Note again that Eq. (38) which is used to compute T_{gear} , contains the *absolute* angular velocity of the gear, not its relative velocity of rotation with respect to the crank. Substituting all the determined quantities into equation (a), we finally obtain

$$T = \frac{1}{12g} (2Q + 9P) l^2 \omega_{cr}^2. \quad (b)$$

Fig. 327.

Now let us compute the elemental work. In this case no external forces do any work, therefore, $dA^e = 0$. The elemental work done by the elastic force of the spring (an internal force) in turning the gear through an angle α about the crank is $dA^i = -M'_{sp} d\alpha = -c \alpha d\alpha$ (the minus sign indicates that the moment is directed opposite the direction through which the gear is turned). As we are seeking the law of motion of the crank, let us express angle α in terms of φ . As $\widetilde{a_2 b} = \widetilde{a_1 b}$, $R\varphi = r\alpha$, whence

$$\frac{\alpha}{R} = \frac{\varphi}{r}, \quad \alpha = \frac{l-r}{r} \varphi \quad \text{and} \quad dA^i = -c \frac{(l-r)^2}{r^2} \varphi d\varphi.$$

Writing now the equation $dT = dA^i$, we have

$$\frac{1}{6g} (2Q + 9P) l^2 \omega_{cr} \cdot d\omega_{cr} = -c \frac{(l-r)^2}{r^2} \varphi d\varphi.$$

Dividing through by dt and taking into account that $\frac{d\varphi}{dt} = \omega_{cr}$ and $\frac{d\omega_{cr}}{dt} = \frac{d^2\varphi}{dt^2}$, we finally obtain the differential equation of motion of the system in the form

$$\frac{d^2\varphi}{dt^2} + k^2\varphi = 0,$$

where

$$k^2 = \frac{6gc(l-r)^2}{(2Q+9P)l^2r^2}.$$

The equation is a differential equation of harmonic motion (§ 123). When moved from its equilibrium position the crank will perform simple harmonic motion the period of which will be

$$\tau = \frac{2\pi}{k} = 2\pi \frac{lr}{l-r} \sqrt{\frac{2Q+9P}{6gc}}.$$

This problem shows the great opportunities for investigating the motion of a system provided by the theorem of the change in kinetic energy.

151. Field of Force. Potential Energy. Amongst the forces which may act on a particle in its interaction with other bodies are also forces dependent only on the position of the particle, i.e., its coordinates x, y, z . For such forces it is convenient to introduce the concept of field of force, or force field. A *field of force* is defined as a region of space in any point of which a particle experiences a force of certain magnitude and direction. An example of a force field is the gravitational field of planets or the sun.

If the work done by the forces of a field in the displacement of a particle depends only on the initial and final positions of the particle, and does not depend on the path followed by the particle, the force field is said to be *conservative*, and the forces acting in that field are called *conservative forces*. Examples of conservative forces are the Newtonian forces of gravitation and elastic forces (§ 113).

When the work done by a force depends on the path or the velocity of the particle to which it is applied, the force is said to be *non-conservative*, or *dissipative*. To such forces belong friction and the resistance of a medium.

For conservative forces we can introduce the concept of *potential energy* as a measure of the capacity of a particle for doing work by virtue of its position in the force field. In order to compare different "capacities for doing work", we must agree on the choice of a zero point O , in which we assume the capacity to do work to be zero (the choice of the zero point, as of any initial point or origin, is arbitrary). The *potential energy of a particle in any configuration M* is defined as the scalar quantity Π equal to the work done on the particle by the forces of a field in the passage from configuration M to the zero configuration:

$$\Pi = A_{(MO)}.$$

It follows from the definition that potential energy is dependent on the position coordinates of the particle M , i.e., that

$\Pi = \Pi(x, y, z)$. To find $\Pi(x, y, z)$, we must calculate $A_{(MO)}$ by the equations of § 112. If it proves impossible to determine the work $A_{(MO)}$ without knowing the path MO or the equation of motion along that path, then the acting force is not a conservative force.

Here are some examples. It follows from the results obtained in § 113 that for the force of gravity, assuming the zero point to be at the origin of a coordinate system and directing axis Oz vertically up, we have (§ 113, section 1)

$$\Pi = pz,$$

where p is the weight of a particle in a gravity field.

Fig. 328.

For the elastic force of a spring which can be extended only in the direction of axis Ox , and choosing the zero point at the end of the unextended spring, we have $\Delta l_{in} = x$, $\Delta l_{fin} = 0$. Therefore, from Eq. (40) in § 113,

$$\Pi = \frac{1}{2} cx^2,$$

where c is the stiffness factor of the spring.

Let us find the expression of work in terms of potential energy. If a particle is moved in a conservative force field from a position M_1 to a position M_2 (Fig. 328), then, as the work does not depend on the path, we will have $A_{(M_1O)} = A_{(M_1M_2)} + A_{(M_2O)}$. But, by definition, $A_{(M_1O)} = \Pi_1$, and $A_{(M_2O)} = \Pi_2$. Hence,

$$A_{(M_1M_2)} = \Pi_1 - \Pi_2. \quad (46)$$

Thus, the work done by a conservative force is equal to the difference between the potential energy values of a moving particle in its initial and final positions. It is evident that the work done by a conservative force in the displacement of a particle along a closed circuit ($\Pi_2 = \Pi_1$) is zero.

Let us demonstrate in conclusion how to determine the force acting in any point of a field of force if the function $\Pi(x, y, z)$ is known. For this let us compute the elemental work dA performed in the displacement of a particle from a point $M(x, y, z)$ to a point $M_1(x + dx, y + dy, z + dz)$. From Eq. (46) we have

$$dA = -d\Pi(x, y, z),$$

as in calculating work we must take the difference between Π and Π_1 , and the differential is the difference between the increased function, i.e., Π_1 , and the initial value of Π .

Substituting dA by its analytical expression (§ 112), and computing $d\Pi$ as a differential function of three variables x, y, z , we have

$$F_x dx + F_y dy + F_z dz = \left(\frac{\partial \Pi}{\partial x} dx + \frac{\partial \Pi}{\partial y} dy + \frac{\partial \Pi}{\partial z} dz \right),$$

from which, equating the factors of dx, dy , and dz , we find

$$F_x = -\frac{\partial \Pi}{\partial x}, \quad F_y = -\frac{\partial \Pi}{\partial y}, \quad F_z = -\frac{\partial \Pi}{\partial z}. \quad (47)$$

Eqs. (47) make it possible, knowing $\Pi(x, y, z)$, to determine the projections of a force acting in a conservative force field, and consequently the force itself. In particular, for the gravitational and elastic forces considered above we obtain, as could be expected,

$$F_x = F_y = 0, \quad F_z = -\frac{\partial \Pi}{\partial z} = -\rho,$$

$$F_x = -\frac{\partial \Pi}{\partial x} = -cx, \quad F_y = F_z = 0.$$

Sometimes in defining a field of force, the function $U(x, y, z) = -\Pi(x, y, z)$, called a *force function*, is introduced in place of Π . For this function, $dA = dU$, and equations of the type (47) do not contain any minus signs.

152. The Law of Conservation of Mechanical Energy. Let us assume that all the external and internal forces acting on a system are conservative forces. Then, for any particle belonging to the system, the work done by the applied forces is

$$A_k = \Pi_{k0} - \Pi_{k1};$$

and for all the external and internal forces

$$\sum A_k = \sum \Pi_{k0} - \sum \Pi_{k1} = \Pi_0 - \Pi_1,$$

where $\Pi = \sum \Pi_k$ is the potential energy of the whole system.

Substituting this expression of work into Eq. (39), we obtain

$$T_1 - T_0 = \Pi_0 - \Pi_1,$$

or

$$T_1 + \Pi_1 = T_0 + \Pi_0 = \text{const.}$$

Thus, in the motion of a system subjected to the action of only conservative forces, the sum of the kinetic and potential energies of the system remains constant for any configuration. This is the law of conservation of mechanical energy, which is a particular case of the general physical law of conservation of energy. The quantity $T + \Pi$ is called the total mechanical energy of the system.

If the acting forces include dissipative forces, such as friction, the total mechanical energy of the system will decrease during its motion due to transformation into other forms of energy, e.g., thermal energy.

The whole meaning of the foregoing law becomes apparent when it is considered in connection with the general physical law of conservation of energy. However, in solving purely mechanical problems, the theorem of the change in the kinetic energy of a system can always be immediately applied.

Example. Consider a pendulum (Fig. 329) displaced through an angle φ_0 from the vertical and released from rest. Then, in its initial position, $\Pi_0 = Pz_0$ and $T_0 = 0$, where P is the weight of the pendulum and z is the coordinate of its centre of gravity. Consequently, neglecting all resisting forces, in any configuration we shall have $\Pi + T = \Pi_0$, or

$$Pz + \frac{1}{2} J_A \omega^2 = Pz_0.$$

Thus, the centre of gravity of the pendulum cannot be higher than position z_0 . When the pendulum swings down, its potential energy decreases and its kinetic energy increases; during an upward swing the potential energy increases and the kinetic energy decreases.

It follows from the previous equation that

$$\omega^2 = \frac{2P}{J_A} (z_0 - z).$$

Thus, the instantaneous angular velocity of a pendulum depends only on the position occupied by its centre of gravity and is always the same for any given configuration.

Such relations occur only during motion under the action of conservative forces.

Due to friction in the axis and the resistance of the air (non-conservative forces), the above relationships do not actually hold; the total mechanical energy of a pendulum decreases with time, and its vibrations are damped.

Fig. 329.

Chapter 28

SOME CASES OF RIGID-BODY MOTION

153. Rotation of a Rigid Body. Let us consider the application of the general theorems of dynamics to some problems on the motion of absolutely rigid bodies. Since the investigation of translatory motion of a rigid body is reduced to particle dynamics, we shall begin with rotational motion.

Let there be a system of given forces $F_1^e, F_2^e, \dots, F_n^e$ acting on a rigid body with a fixed axis of rotation z (Fig. 330). Also acting on the body are the reactions R_A and R_B of the bearings. To exclude these immediately unknown forces from the equations of motion, we make use of the theorem of moments with respect to axis z (§ 144). As the moments of forces R_A and R_B with respect

to the axis are zero, we have

$$\frac{dK_z}{dt} = M_z^e$$

where

$$M_z^e = \sum m_k (F_k^e)_z.$$

We shall call the quantity M_z^e the *turning moment*, or *torque*.

Substituting the expression $K_z = J_z \omega$ into the foregoing equation, we obtain

$$J_z \frac{d\omega}{dt} = M_z^e \quad \text{or} \quad J_z \frac{d^2\varphi}{dt^2} = M_z^e. \quad (48)$$

Eq. (48) is the differential equation of the rotational motion of a rigid body. It follows from the equation that the product of the moment of inertia of a body with respect to its axis of rotation and its angular acceleration is equal to the turning moment:

$$J_z \varepsilon = M_z^e. \quad (48')$$

Equation (48') shows that, for a given torque M_z^e , the greater the moment of inertia of a body, the less the angular velocity, and vice versa. Thus we see that in rotational motion the moment of inertia of a body actually plays the same role as mass in translatory motion, i.e., it is the measure of a body's inertia in rotational motion (see § 131).

Eq. (48) can be applied: 1) to develop the equation of rotation of a body $\varphi = f(t)$ or to find its angular velocity ω if the applied torque is known, 2) to determine the torque M_z^e if the law of motion, i.e., $\varphi = f(t)$, is known. In solving the first problem it should be borne in mind that in the general case M_z^e may be a variable dependent on t , φ , and $\omega = \frac{d\varphi}{dt}$.

Instead of Eq. (48), rotational motion may be investigated with the help of the theorem of the change in kinetic energy: $T_1 - T_0 = A^e$, where T and A^e are found from Eqs. (37) and (43).

Note the following special cases:

- 1) If $M_z^e = 0$, $\omega = \text{const.}$, i.e., the rotation is *uniform*;
- 2) If $M_z^e = \text{const.}$, $\varepsilon = \text{const.}$, i.e., the rotation is *uniformly variable*.

Eq. (48) is analogous in form to the differential equation of rectilinear motion of a particle (§ 104); therefore the methods of integration are also analogous (see Problem 143).

Fig. 330.

Eq. (48) is most conveniently used in problem solutions when a system consists *only* of a single rotating body. If a system has, besides a rotating body, other moving bodies (as, for instance, in Problems 133, 138, and others), the equation of motion is more conveniently developed with the help of the general theorems or the methods which will be described below in §§ 160 and 167.

In solving problems of the type 133 on p. 338 with the help of Eq. (48) a common mistake is to write the equation in the form $J_O \varepsilon = Qr$. Actually, though, acting on the drum is not the force Q but the tension in the string F , which is not equal to Q , and Eq. (48) takes the form $J_O \varepsilon = Fr$. To solve it, F must be found additionally from the equation of motion of the load A , which makes the computations longer.

Fig. 331.

Problem 142. A wheel of radius R and weight P rotates on its axis O with an angular velocity ω_0 (Fig. 331). A brake shoe is applied to the wheel at some instant with a force Q . The coefficient of friction of the shoe on the wheel is f . Neglecting friction in the axle and the weight of the spokes, determine in how many seconds the wheel will stop.

Solution. Writing Eq. (48) and considering the moment positive in the direction of the rotation, we have

$$J_O \frac{d\omega}{dt} = -fQr, \quad (a)$$

as the force of friction $F = fQ$. From this, integrating, we obtain

$$J_O \omega = -fQrt + C_1.$$

According to the initial conditions, at $t = 0$, $\omega = \omega_0$, consequently $C_1 = J_O \omega_0$, and finally

$$\omega = \omega_0 - \frac{fQr}{J_O} t.$$

At $t = t_1$, when the wheel stops, $\omega = 0$. Substituting this expression and taking into account that for the rim (a ring) $J_O = \frac{P}{g} r^2$, we obtain

$$t_1 = \frac{J_O \omega_0}{fQr} = \frac{Pr\omega_0}{fQg}.$$

If we want to determine the number of revolutions of the wheel until it stops, it is more convenient to apply the theorem of the change in kinetic energy without integrating equation (b) again.

Problem 143. A vertical cylindrical rotor whose moment of inertia with respect to its axis is J_z (Fig. 332) is made to revolve by an applied torque M_t . Determine how the angular velocity ω of the rotor will change during the motion if $\omega_0 = 0$ and the moment of the resisting force of the air is proportional to ω , i.e., $M_{res} = \mu\omega$.

Solution. The differential equation (48) of the rotation of the rotor has the form (assuming the moments in the direction of rotation to be positive)

$$J_z \frac{d\omega}{dt} = M_t - \mu\omega.$$

Separating the variables and assuming $\frac{\mu}{J_z} = n$, we have

$$-\mu \frac{d\omega}{M_t - \mu\omega} = -n dt,$$

whence, integrating, we find

$$\ln(M_t - \mu\omega) = -nt + \ln C.$$

As, at $t = 0$, $\omega = 0$, then $C = M_t$, and

$$\ln \frac{M_t - \mu\omega}{M_t} = -nt,$$

or

$$\frac{M_t - \mu\omega}{M_t} = e^{-nt}.$$

And finally we obtain

$$\omega = \frac{M_t}{\mu} (1 - e^{-nt}).$$

The angular velocity of the rotor increases with time and tends towards the limiting value $\omega_{\lim} = \frac{M_t}{\mu}$.

Fig. 332.

154. The Compound Pendulum. Any rigid body free to oscillate about a fixed horizontal axis under the action of gravity is called a *compound*, or *physical*, *pendulum*. Let Fig. 333 denote a cross section of a pendulum normal to the axis of support through the centre of mass C of the pendulum, and let us introduce the notation P for the weight of the pendulum, a for the distance OC from the centre of mass to the axis of suspension, and J_o for the moment of inertia of the pendulum with respect to the axis of suspension. We shall specify the position of the pendulum by the angle φ that OC makes with the vertical.

Fig. 333.

To develop the equation of motion of the pendulum, we shall employ the differential equation of rotational motion (48). In our case $M_z = M_o = -Pa \sin \varphi$ (the minus being taken to indicate that the direction of the moment is opposite to the positive direction of angle φ), and Eq. (48) takes the form

$$J_o \frac{d^2\varphi}{dt^2} = -Pa \sin \varphi.$$

Dividing through by J_o and introducing the notation

$$\frac{Pa}{J_o} = k^2,$$

we obtain the differential equation of motion of the pendulum in the form

$$\frac{d^2\varphi}{dt^2} + k^2 \sin \varphi = 0.$$

The equation is of the same form as the differential equation for a simple pendulum (§ 124), and we conclude that the oscillation of a compound pendulum is of the same type as of a simple pendulum.

Considering only small oscillations and assuming approximately $\sin \varphi \approx \varphi$, we obtain the differential equation for small oscillations in the form

$$\frac{d^2\varphi}{dt^2} + k^2 \varphi = 0.$$

This is the differential equation of simple harmonic motion, consequently, like a simple pendulum, a compound pendulum making small oscillations is in simple harmonic motion. The period of small oscillations is

$$T_{\text{compound}} = \frac{2\pi}{k} = 2\pi \sqrt{\frac{J_o}{Pa}}. \quad (49)$$

Comparing Eq. (49) with the formula for the period of small oscillations of a simple pendulum

$$T_{\text{simple}} = 2\pi \sqrt{\frac{l}{g}},$$

we find that for a length

$$l_1 = \frac{J_o g}{Pa} = \frac{J_o}{Ma} \quad (50)$$

the period of oscillation of a simple pendulum is equal to that of an equivalent compound pendulum.

The length l_1 of such a simple pendulum whose period of oscillation is equal to that of a given compound pendulum is called the *equivalent length of the compound pendulum*. The point K which lies at a distance $OK = l_1$ from the axis of support is called the *centre of oscillation*, or the *centre of percussion*, of the compound pendulum (see Fig. 333).

Noting that, from the parallel-axis theorem, $J_o = J_c + Ma^2$, we can transform Eq. (50) to the form

$$l_1 = a + \frac{J_c}{Ma}. \quad (50')$$

It follows from this that OK is always greater than $OC = a$, i.e., that the centre of percussion of a compound pendulum is always located below its centre of mass.

We see from Eq. (50') that $KC = J_C/Ma$. Therefore, if the axis of suspension passes through point K , the equivalent length l_2 of the resulting pendulum will, by Eq. (50'), be

$$l_2 = KC + \frac{J_C}{M(KC)} = \frac{J_C}{Ma} + a = l_1.$$

Consequently, points K and O are interchangeable, i.e., if the axis of suspension passes through K , the centre of percussion will be at O (as $l_2 = l_1$), and the period of oscillation will not change. This property is employed in the so-called inverted pendulum which is used to determine the acceleration of gravity.

155. Determination of Moments of Inertia by Experiment. One of the methods of determining the moment of inertia of bodies by experiment is based on the application of Eq. (49) for the period of small oscillations.

Let it be required to determine the moment of inertia with respect to an axis Oz of a connecting rod of weight P (Fig. 334). For this the body is suspended so that the axis Oz is horizontal, and the period of small oscillations T is determined by direct observation. Then the distance $OC = a$ is found by the method of weighing (see § 55, Fig. 129). Substituting the obtained values into Eq. (49), we have

$$J_{Oz} = \frac{PaT^2}{4\pi^2}.$$

Fig. 334.

If it is required to determine the moment of inertia of a body with respect to an axis Ox through its centre of gravity, the body may be suspended by two strings so that the axis Ox is horizontal (Fig. 335) and the moment of inertia J_{AB} determined with respect to axis AB (the value of a is immediately known). Then the required moment of inertia is computed by the parallel-axis theorem:

$$J_{Ox} = J_{AB} - \frac{P}{g} a^2.$$

156. Plane Motion of a Rigid Body. The position of a body performing plane motion is specified at any instant by the position of any pole and the angle of rotation of the body about that pole (§ 77). Dynamical problems are much more simply solved if the centre of mass C of a body is taken as the pole (Fig. 336) and the position of the body is defined by coordinates x_C, y_C , and angle φ .

Let there be acting on the body a set of external forces $F_1^e, F_2^e, \dots, F_n^e$. The equation of motion of point C can be found from the theorem of the motion of centre of mass:

$$M\omega_C = \sum F_k^e, \quad (51)$$

and the rotation about C is given by Eq. (48), since the theorem from which it was developed is also valid for the motion of a

Fig. 335.

Fig. 336.

system about the centre of mass. Finally, after projecting both sides of Eq. (51) on the coordinate axes, we obtain

$$M\omega_{Cx} = \sum F_{kx}^e, \quad M\omega_{Cy} = \sum F_{ky}^e, \quad J_C \varepsilon = \sum m_C (F_k^e). \quad (52)$$

or

$$M \frac{d^2 x_C}{dt^2} = \sum F_{kx}^e, \quad M \frac{d^2 y_C}{dt^2} = \sum F_{ky}^e, \quad J_C \frac{d^2 \varphi}{dt^2} = \sum m_C (F_k^e) \quad (52')$$

Eqs. (52) are the differential equations of plane motion of a rigid body. With their help we can develop the equation of motion of a body if the forces are given, or we can determine the principal vector and principal moment of the acting forces if the law of motion is known.

For the case of constrained motion, when the path of the centre of mass is known, the equation of motion of point C is more conveniently expressed in terms of the projections on the tangent τ and principal normal n to the path. Then, instead of the equations (52), we obtain

$$M \frac{dv_C}{dt} = \sum F_{k\tau}^e, \quad M \frac{v_C^2}{\rho_C} = \sum F_{kn}^e, \quad (53)$$

$$J_C \frac{d^2 \varphi}{dt^2} = \sum m_C (F_k^e),$$

where ρ_C is the radius of curvature of the path of the centre of mass.

Note that in constrained motion the right sides of Eqs. (52) or (53) will additionally include the unknown reactions of the constraints. They will have to be determined by developing additional equations describing the conditions of motion imposed on the body by the constraints (see Problem 144 and others). The equations of constrained motion will often be more conveniently developed with the help of the theorem of the change in kinetic energy, which can be used in place of one of the equations (52) or (53).

Problem 144. A uniform circular cylinder rolls down an inclined plane without slipping (Fig. 337). Neglecting rolling friction, determine the acceleration of the centre of the cylinder and the limiting friction of impending slip.

Solution. Let us introduce the following notations: α for the angle of inclination of the surface, P for the weight of the cylinder, R for its radius, and F for the limiting friction of impending slip; let us also direct the x axis along the inclined plane and the y axis perpendicular to it.

As the centre of mass of the cylinder does not move parallel to the y axis, $\omega_{Cy} = 0$, and the sum of the projections of all the forces on the y axis is also zero. Thus,

$$N = P \cos \alpha.$$

In writing the last two of the equations (52), take into account that $\omega_{Cx} = \omega_C$. Neglecting rolling friction and taking the direction of rotation of the cylinder as the positive direction of the moment of force, we find

$$M\omega_C = P \sin \alpha - F, \quad J_C \epsilon = FR. \quad (a)$$

Equations (a) contain three unknown quantities, ω_C , ϵ , and F (we cannot consider $F = fN$ here, because this equality is valid only when the point of contact *slides* on the surface; when there is no sliding it is possible for $F \leq fN$; see § 36). We obtain an additional relationship between the unknown quantities if we take into account that in pure rolling $v_C = \omega R$, whence, differentiating, we obtain $\omega_C = \epsilon R$. Then, remembering that for a uniform cylinder $J_C = 0.5MR^2$, the second of equations (a) takes the form

$$\frac{1}{2} M\omega_C = F. \quad (b)$$

Substituting this expression of F into the first of equations (a), we obtain

$$\omega_C = \frac{2}{3} g \sin \alpha. \quad (c)$$

Now from (b) we find

$$F = \frac{1}{3} P \sin \alpha. \quad (d)$$

This is the frictional force that must act on the rolling cylinder if it is not to slip. It was pointed out before that $F \leq fN$. Consequently, pure rolling takes place when

$$\frac{1}{3} P \sin \alpha \leq [P \cos \alpha]$$

Fig. 337.

or

$$f \geq \frac{1}{3} \tan \alpha.$$

If the coefficient of friction is less than this, force F cannot attain the value given by equation (d), and the cylinder will slip. In this case v_C and ω are not related by the equality $v_C = \omega R$ (the point of contact is not the instantaneous centre of zero velocity), but now F has a limiting value, i.e., $F = fN = fP \cos \alpha$, and equations (a) take the form,

$$\frac{P}{g} \omega_C = P (\sin \alpha - f \cos \alpha), \quad \frac{1}{2} \frac{P}{g} R^2 \epsilon = f P R \cos \alpha,$$

whence

$$\omega_C = g (\sin \alpha - f \cos \alpha); \quad \epsilon = \frac{2gf}{R} \cos \alpha. \quad (e)$$

In this case the centre of the cylinder moves with an acceleration ω_C , while the cylinder itself rotates with an angular acceleration ϵ , the values of which are determined from equations (e).

Problem 145. Solve the previous problem taking into account the resistance to rolling, assuming the coefficient of rolling friction to be k .

Solution. In order to give an example of another method of computation, let us find ω_C with the help of the theorem of the change in kinetic energy, i.e., the equation

$$dT = dA^e, \quad (a)$$

In our case (see Problem 134, § 147),

$$T = \frac{3}{4} M v_C^2.$$

Only the force P and the resisting moment perform any work. The work done by forces F and N in rolling is zero (see § 149). Then, taking into account Eq. (45), we obtain (see Fig. 337, but now with force N shifted by the value k in the direction of the motion):

$$dA^e = P \sin \alpha \cdot ds_C - \frac{k}{R} N ds_C = P \left(\sin \alpha - \frac{k}{R} \cos \alpha \right) ds_C.$$

Substituting the determined quantities into equations (a) and dividing through by dt , we have

$$\frac{3}{2} \frac{P}{g} v_C \frac{dv_C}{dt} = P \left(\sin \alpha - \frac{k}{R} \cos \alpha \right) \frac{ds_C}{dt}.$$

The last multiplier is equal to v_C , and we finally obtain

$$\omega_C = \frac{2}{3} g \left(\sin \alpha - \frac{k}{R} \cos \alpha \right).$$

At $k=0$ this formula gives the result of the previous problem.

The frictional force can now be found from the equation $M\omega_C = P \sin \alpha - F$, which does not change its form.

Problem 146. A uniform cylinder of weight P and radius r starts rolling from rest without slipping from a point on a cylindrical surface of radius R defined by angle φ_0 (Fig. 338).

Determine: 1) The pressure of the cylinder on the surface for any angle φ ; 2) The law of motion of the cylinder when angle φ_0 is small. Neglect rolling friction.

Solution. 1) Acting on the cylinder in any position is force P , the normal reaction N , and the frictional force F , without which rolling is impossible. The path of the centre C is known: a circle of radius $R - r$. To determine N we make use of the second of equations (53). Directing the normal Cn inwards to the path, we obtain

$$M \frac{v_C^2}{R - r} = N - P \cos \varphi. \quad (a)$$

The quantity v_C in this equation can be found from the theorem of the change in kinetic energy (compare with § 118):

$$T - T_0 = \sum A_k^e. \quad (b)$$

Fig. 338.

In our case $T_0 = 0$ and $T = \frac{3}{4} M v_C^2$ (see Problem 134). Only force P does any work, consequently,

$$\sum A_k^e = P h = P (R - r) (\cos \varphi - \cos \varphi_0),$$

and equation (b) takes the form

$$\frac{3}{4} M v_C^2 = P (R - r) (\cos \varphi - \cos \varphi_0). \quad (c)$$

Computing from here $M v_C^2$ and substituting into equation (a), we obtain finally

$$N = \frac{P}{3} (7 \cos \varphi - 4 \cos \varphi_0).$$

If, for example, $\varphi_0 = 60^\circ$ and $\varphi = 0^\circ$, then $N = \frac{5}{3} P$.

2) To determine the law of motion of point C , differentiate equation (c) with respect to time. We obtain

$$\frac{3}{2} \frac{P}{g} v_C \frac{d v_C}{d t} = -P (R - r) \sin \varphi \frac{d \varphi}{d t}.$$

In our case angle, φ decreases when the cylinder moves, and $\frac{d \varphi}{d t} < 0$. Then,

$$v_C = (R - r) \left| \frac{d \varphi}{d t} \right| = -(R - r) \frac{d \varphi}{d t}; \quad \frac{d v_C}{d t} = -(R - r) \frac{d^2 \varphi}{d t^2}.$$

Substituting these expressions into the previous equation, we obtain finally

$$\frac{d^2 \varphi}{d t^2} + \frac{2}{3} \frac{g}{R - r} \sin \varphi = 0.$$

If angle φ_0 is small, then, as $\varphi \leq \varphi_0$, we can assume that $\sin \varphi \approx \varphi$, and the equation takes the form

$$\frac{d^2 \varphi}{d t^2} + k^2 \varphi = 0,$$

where

$$k^2 = \frac{2}{3} \frac{g}{R-r}.$$

Consequently (see § 123), the centre of the cylinder performs simple harmonic motion, its period being

$$\tau = \frac{2\pi}{k} = 2\pi \sqrt{\frac{3(R-r)}{2g}}.$$

Problem 147. The body in Fig. 339 rests at B on a piezoelectric sensor of an instrument for measuring pressure, and at A it is attached to a string AD .

When the system is in equilibrium, AC is horizontal and the pressure at B is Q_0 . Determine the moment of inertia J_C of the body with respect to an axis through the centre of mass C , if at the instant when the string is severed the pressure at B becomes Q_1 and the distance l is known.

Solution. 1) In the equilibrium position $Q_0 l = P(l-a)$, whence

$$a = \frac{P - Q_0 l}{P} l.$$

Fig. 339.

2) When the string is severed, the body begins plane motion. Its displacement in the initial time increment can be neglected. Then Eqs. (52), which are valid only for this initial time interval, will take the form

$$M\omega_{Cx} = P - Q_1, \quad \omega_{Cy} = 0, \quad J_C \varepsilon = Q_1 a. \quad (a)$$

As $\omega_{Cy} = 0$, point C starts moving vertically down and point B slides horizontally (assuming the friction in the support to be very small). Erecting perpendiculars to the directions of these displacements, we find that the instantaneous centre of zero velocity is at point K . Consequently, $v_C = a\omega$. Assuming $a = \text{const.}$ for the elementary time interval, we obtain, after differentiating, $\omega_C = a\varepsilon$. Then the first of equations (a) gives

$$\frac{P}{g} a \varepsilon = P - Q_1.$$

Determining ε from here, we obtain finally

$$J_C = \frac{Q_1 a}{\varepsilon} = \frac{P}{g} \frac{Q_1}{P - Q_1} a^2.$$

This result can be used for the experimental determination of moment of inertia.

Problem 148. The weight of a motor car together with its wheels is P , the weight of each wheel is p , and their radii are r (Fig. 340). Acting on the rear (driving) wheels is a turning moment M_r . The car starts from rest and is subjected to the resistance of the air, which is proportional to the square of the translatory velocity: $R = \mu v^2$. The frictional moment acting on the axle of each wheel is M_{fr} . Neglecting rolling friction, determine 1) the maximum velocity of the car; 2) the sliding friction acting on the driving and driven wheels during motion.

Solution. 1) To determine the maximum velocity, write the equation of motion from Eq. (40):

$$dT = dA^e + dA^i. \quad (a)$$

Fig. 340.

The kinetic energy of the car is equal to the energy of the body plus the energy of the wheels. Taking into account that P is the weight of the whole car and $v_C = \omega r$, and denoting the radius of gyration of each wheel by the symbol ρ , we obtain

$$T = \frac{1}{2} \frac{P}{g} v_C^2 + 4 \left(\frac{1}{2} J_C \omega^2 \right) = \frac{1}{2g} \left(P + 4\rho \frac{\rho^2}{r^2} \right) v_C^2.$$

Of all the external forces, only the resistance of the air does work, as we have neglected rolling resistance, and in this case the work done by the frictional forces F_1 and F_2 of the wheels on the road is zero (see § 149). Therefore,

$$dA^e = -\mu v_C^2 ds_C.$$

The work done by the internal forces (the torque and the friction in the axles) is

$$dA^i = (M_t - 4M_{fr}) d\varphi = (M_t - 4M_{fr}) \frac{ds_C}{r}.$$

Substituting all these expressions into equation (a) and dividing through by dt , we obtain

$$\frac{1}{g} \left(P + 4\rho \frac{\rho^2}{r^2} \right) v_C \frac{dv_C}{dt} = \frac{1}{r} (M_t - 4M_{fr} - \mu r v_C^2) \frac{ds_C}{dt},$$

from which, cancelling out $v_C = \frac{ds_C}{dt}$, we find

$$\left(P + 4\rho \frac{\rho^2}{r^2} \right) \omega_C = \frac{g}{r} (M_t - 4M_{fr} - \mu r v_C^2). \quad (b)$$

When the velocity reaches its limiting value, the acceleration ω_C becomes zero. Therefore v_C^{lim} can be found from the equation

$$M_t - 4M_{fr} - \mu r v_C^2 = 0,$$

whence

$$v_C^{\text{lim}} = \sqrt{\frac{M_t - 4M_{fr}}{\mu r}}.$$

This result could have been obtained immediately by equating the total work done by all the forces to zero. The purpose of the above computations was to show how to develop the equation of motion (b).

2) To determine the frictional forces acting on each wheel, we deduce the equations of the rotation of the wheels about their axes. For the driving wheels, taking into account that the frictional force F_1 acting on each of them is directed forward (see § 136, Fig. 301), we obtain

$$2 \frac{P}{g} \rho^2 \epsilon = M_t - 2M_{fr} - 2F_1 r.$$

Since in rolling $\omega_C = \epsilon r$, we obtain finally

$$F_1 = \frac{0.5M_t - M_{fr}}{r} - \frac{\rho^2}{r^2} \frac{P}{g} \omega_C. \quad (c)$$

The frictional force F_2 acting on each of the driven wheels is directed backwards. Therefore, for the driven wheels we have

$$\frac{P}{g} \rho^2 \epsilon = F_2 r - M_{fr}.$$

whence

$$F_2 = \frac{M_{fr}}{r} + \frac{\rho^2}{r^2} \frac{\rho}{g} \omega_C. \quad (d)$$

We see from equation (b) that when the velocity increases the acceleration ω_C decreases and tends to zero.

Thus, the frictional forces acting on the driving wheels increase somewhat during the acceleration and reach a maximum value when the motion becomes uniform ($\omega_C = 0$). If we substitute the value of ω_C from equation (b), we shall readily notice that the last component in equation (c) is much smaller than the first, since $P \gg \rho$. Therefore, for all practical purposes the value of F_1 changes only slightly.

The frictional forces acting on the driven wheels will be greatest at the beginning of the motion, then decreasing till they reach their smallest value M_{fr}/r when the motion is uniform ($\omega_C = 0$).

If the coefficient of friction of the wheels on the road is too small for the frictional force to reach the values of F_1 , or F_2 , the respective wheels will slip.

As M_t is much larger than M_{fr} , the driving wheels are primarily in danger of slipping.

When the motor is switched off, all the wheels become driven, and initially they will all be subjected to the frictional force $F = M_{fr}/r$. The action of brake shoes is equivalent to an increase of M_{fr} acting on the axles, and consequently of the frictional force acting on each wheel, and the motor car slows down quicker (see § 136).

Fig. 341.

157. Approximate Theory of Gyroscopic Action. A gyroscope, or top, is a rigid body possessing an axis of material symmetry, the body being fixed to some point O on that axis. In gyroscopic instruments, the gyroscope is usually supported in a system of concentric rings or gimbals (Fig. 341) in such a way that, no matter how it is

turned, its centre of gravity remains motionless.

Gyroscopes used in engineering have a high angular velocity ω_1 of spin about the axis of symmetry (axis of spin). This makes it possible to neglect in the first approximation the additional rotations of the gyroscope due to the motion of its axis, and to develop an approximate theory of gyroscopic action.

The principal angular-momentum vector K_0 of a body rotating about a *fixed* axis of symmetry Oz is directed along the axis of spin (see § 143) and is computed according to Eq. (32). The basic assumption in the elementary theory of gyroscopic action is that even if the axis *slowly* moves, at any instant the principal angular-momentum vector K_0 of a gyroscope with respect to its fixed point remains directed along the axis of spin in the same

direction as vector ω_1 , and is equal to $J_z \omega_1$:

$$K_O = K_z = J_z \omega_1, \quad (54)$$

where J_z is the moment of inertia of the gyroscope with respect to its axis of symmetry. The faster the spin of the gyroscope, the more valid this assumption.

Proceeding from this assumption, let us examine the main properties of the gyroscope.

1. **Free Gyroscope.** Consider a gyroscope supported at its centre of gravity O (see Fig. 341). Then, neglecting friction in the axles of the gimbals, we have $\sum m_O(F_k^e) = 0$ and $K_O = \text{const.}$, i.e., the vector of the total angular momentum is constant both in magnitude and direction (see § 145). But as vector K_O is directed continually along the axis of spin, it follows that *the axis of a free gyroscope remains constantly aligned in space with respect to an inertial (stellar) frame of reference.* This is one of the important properties of gyroscopic action which is employed in all gyroscopic instruments.

By virtue of this property, the axis of a free gyroscope will rotate relative to the earth in the opposite direction of the latter's rotation. A free gyroscope can thus be used to prove the fact of the earth's rotation round its axis. Such an experiment was first carried out by Foucault in 1852.

2. **Action of a Force Applied to the Axis of a Gyroscope.** Let a force F whose moment with respect to the centre O is $M_O = Fh$ start acting on the axis of a rapidly spinning gyroscope (Fig. 342). Then, by the principle of moments (§ 144):

$$\frac{dK_O}{dt} = M_O \quad \text{or} \quad \frac{d(\overline{OB})}{dt} = M_O,$$

where B is a point on the axis coincident with the end of vector K_O . From this, taking into account that the derivative of vector \overline{OB} with respect to time gives the velocity v_B of point B , we obtain

$$v_B = M_O. \quad (55)$$

Thus, point B , and with it the axis of the gyroscope, will move in the direction of vector M_O . We find, therefore, that *if a force is made to act on the axis of a rapidly spinning gyroscope, the axis starts moving not in the direction of the acting force but*

Fig. 342.

in the direction of the vector of the moment of the force with respect to the fixed point O of the gyroscope, i.e., perpendicular to the force*.

Note that if the gyroscope were made to spin in the opposite direction (see Fig. 342), vector ω_1 , and with it vector K_O applied at point O , would be directed downward, and the lower end of the gyroscope would move in the direction of M_O , i.e., towards us, and the upper end in the direction of the page.

Another important result follows from Eq. (55). When the action of the force ends, M_O , and consequently v_B as well, vanish and the gyroscope axis stops. Thus, a gyroscope does not retain the motion imparted to it by a force. If the force is of short duration (an impact), the gyroscope axis will practically not change its orientation. This is the cause of the *stability* of the axis of a rapidly spinning gyroscope.

Fig. 343.

3. Regular Precession of a Heavy Gyroscope. Let us consider a gyroscope whose fixed point O is not coincident with its centre of gravity C (Fig. 343). In this case continuously acting on the axis of spin will be a force P which,

as just shown, will deflect the axis Oz not downwards (not in the direction of angle α increasing), but in the direction of $m_O(P)$, i.e., normal to plane Ozz_1 . As a result, the axis of spin will turn about the vertical axis Oz_1 , describing a conical surface. This motion of the axis of a gyroscope is called *precession*.

Let us find the angular velocity ω_2 of the precession. From Eq. (55), we should have $v_B = M_O$. Introducing the notation $OC = a$, we find that in this case $M_O = Pa \sin \alpha$. On the other hand, $v_B = \omega_2 \cdot BD = \omega_2 \cdot OB \sin \alpha = \omega_2 \cdot K_O \sin \alpha$, or, taking into account Eq. (54),

$$v_B = J_z \omega_1 \omega_2 \sin \alpha. \quad (56)$$

Consequently, $J_z \omega_1 \omega_2 \sin \alpha = Pa \sin \alpha$, whence

$$\omega_2 = \frac{Pa}{J_z \omega_1}. \quad (57)$$

As ω_1 is large, the angular velocity of precession is small. As ω_1 decreases, ω_2 increases, a phenomenon which is familiar to anyone who has ever seen a spinning top.

The earth's axis also performs motion of precession, due to the fact that the earth is not an ideal sphere and also to the incli-

* How the direction of vector M_O is determined was explained in § 41.

nation of its axis, thanks to which the resultant of the attractive forces of the sun and the moon does not pass through the earth's centre of mass, producing some moments with respect to the centre. The rate of precession of the earth's axis (the time of one complete revolution) is approximately 26,000 years.

4. The Gyroscopic Effect. Consider a rapidly spinning gyroscope supported by bearings A and A' in a gimbal ring which in turn can rotate with an angular velocity ω_2 ($\omega_2 \ll \omega_1$) about axis DD' (Fig. 344). Since under such conditions the gyroscope axis precesses, point B (the end of vector K_O), as in the previous case, will have an angular velocity v_B defined by Eq. (56). From Eq. (55) we conclude that acting on the axis is a moment of magnitude

$$M_O = v_B = J_z \omega_1 \omega_2 \sin \alpha.$$

This moment is, evidently, created by forces Q, Q' with which the bearings A and A' act on the axis. As the centre of mass of the gyroscope is fixed, these couples form a couple whose moment M_O must be directed the same as the velocity v_B , i.e., upward (towards the reader in Fig. 344).

But then the axis of the gyroscope will also press on bearings A and A' with forces N, N' equal in magnitude to forces Q, Q' , but oppositely directed.

The force couple (N, N') is called a *gyroscopic couple*, and its moment the *gyroscopic moment*. Since in magnitude $M_{\text{gyr}} = M_O$, then

$$M_{\text{gyr}} = J_z \omega_1 \omega_2 \sin \alpha. \quad (58)$$

We deduce from this Zhukovsky's Rule: *If a forced precession is imparted to a rapidly spinning gyroscope, a couple of moment M_{gyr} will start to act on the bearings which will tend to move the axis of spin along the shortest path to set it parallel to the axis of precession, so that the directions of vectors ω_1 and ω_2 would coincide.*

Besides bringing forces to act on the bearings, the gyroscopic effect may cause the body to which the bearings are attached to move too, if the motion is not opposed by constraints.

Consider the following example. If the rotor of a ship's turbine rotates with an angular velocity ω_1 (Fig. 345) and the ship turns with an angular velocity ω_2 , gyroscopic forces N_1 and N_2

Fig. 344.

will be acting on bearings A and B , directed as shown in the diagram*. If $AB=l$ and the moment of inertia of the rotor is J_z , then, by Eq. (58),

$$M_{\text{gyr}} = Nl = J_z \omega_1 \omega_2 \text{ and } N = \frac{J_z \omega_1 \omega_2}{l}.$$

These forces may reach a value of several tons and they must be taken into account in calculating the bearings. Through the bearings the gyroscopic forces are transmitted to the hull, and if the vessel is very light they can cause the stern or bow to "dip" during a turn. A similar phenomenon takes place when a propeller aircraft banks in a horizontal plane.

The gyroscopic phenomena discussed in this section are used for gyroscopic stabilisers, navigation and other special instruments.

Fig. 345.

An example of a direct action gyroscopic stabiliser is the ship anti-rolling gyroscope. This is a heavy gyroscope (Fig. 346) whose axis of spin AA_1 is mounted in a frame the axis of rotation DD_1 of which is attached to the ship's hull. When the ship starts to roll and a moment M starts to act on it, a specially controlled motor begins to turn the frame with a certain angular velocity ω_2

Fig. 346.

Fig. 347.

(see diagram). As a result a gyroscopic couple (N, N') of moment $J\omega_1\omega_2$ is brought to act on bearings D and D_1 , which reduces the roll. When the moment M changes its direction, the motor will reverse the rotation of the frame and the couple (N, N') will also change its sense.

Another gyroscopic stabiliser (not a direct-action one, though) is a device which controls the motion of a torpedo in the horizontal plane. The stabilising element is a free gyroscope (see Fig. 341), whose axis is coincident with the axis of the torpedo, which is directed to the target at the launching moment. If the torpedo departs from its set course by an angle α (Fig. 347), the gy-

* Gyroscopic forces also appear in the bearings due to rolling and pitching of the ship. Their directions, of course, are different.

roscope axis will continue, by virtue of the property of a free gyroscope, to point towards the target and will therefore turn through the same angle with respect to the axis of the torpedo. This turn actuates a governor which controls the steering mechanism. The rudder will turn correspondingly and the torpedo will return to its course. A similar idea is incorporated in automatic pilots, which sense any deflection of an aircraft from its set course and actuate the necessary steering assemblies.

To other gyroscopic navigation instruments belong the gyro-compass, the gyro-horizon, the turn-indicator, and others. They are of various design, but all of them are based on the properties of the gyroscope discussed here.

Chapter 29

D'ALEMBERT'S PRINCIPLE. FORCES ACTING ON THE AXIS OF A ROTATING BODY

158. **D'Alembert's Principle for a System.** Consider a system of n particles. Let us select any particle of mass m_k and denote the resultants of all the external and internal forces applied to it by the symbols F_k^{ext} and F_k^{int*} . If we add to these forces the inertia force $F_k^i = -m_k \omega_k$, then according to D'Alembert's principle for a single particle (§ 119), the force system F_k^{ext} , F_k^{int} , F_k^i will be in equilibrium, and consequently,

$$F_k^{ext} + F_k^{int} + F_k^i = 0.$$

Reasoning similarly for all the particles of the system, we arrive at the following result, which expresses D'Alembert's principle for a system: *If at any moment of time to the effective external and internal forces acting on every particle of a system are added the respective inertia forces, the resultant force system will be in equilibrium and all the equations of statics will apply to it.*

We know from statics that the geometrical sum of balanced forces and the sum of their moments with respect to any centre O are zero; we know, further, from the principle of solidification, that this holds good not only for forces acting on a rigid body, but for any deformable system. Thus, according to D'Alembert's principle, we must have

$$\begin{aligned} \sum (F_k^{ext} + F_k^{int} + F_k^i) &= 0; \\ \sum [m_o (F_k^{ext}) + m_o (F_k^{int}) + m_o (F_k^i)] &= 0. \end{aligned}$$

* We introduce the notation F^{int} (and F^{ext}) for internal and external forces in this chapter to avoid confusion between *internal* forces and *inertia* forces, for which the notation F^i is retained.

Let us introduce the following notation:

$$\mathbf{R}^i = \sum \mathbf{F}_k^i; \quad \mathbf{M}_O^i = \sum m_O (\mathbf{F}_k^i). \quad (59)$$

The quantities \mathbf{R}^i and \mathbf{M}_O^i are respectively the *principal vector* of the inertia forces and their *principal moment with respect to a centre O*. Taking into account that the sum of the internal forces and the sum of their moments are each zero (§ 129), we obtain

$$\sum \mathbf{F}_k^{ext} + \mathbf{R}^i = 0; \quad \sum m_O (\mathbf{F}_k^{ext}) + \mathbf{M}_O^i = 0. \quad (60)$$

Use of Eqs. (60), which follow from D'Alembert's principle, simplifies the process of problem solution because the equations do not contain the internal forces. Actually Eqs. (60) are equivalent to the equations expressing the theorems of the change in the momentum and the total angular momentum of a system, differing from them only in form.

Eqs. (60) are especially convenient in investigating the motion of a rigid body or a system of rigid bodies. For the complete investigation of any deformable system these equations, however, are insufficient*.

For the projections on a set of coordinate axes, Eqs. (60) give equations analogous to the corresponding equations of statics (see §§ 24 and 48). To use these equations for solving problems we must know the principal vector and the principal moment of the inertia forces.

159. The Principal Vector and the Principal Moment of the Inertia Forces of a Rigid Body. It follows from Eqs. (59) (see § 46) that a system of inertia forces applied to a rigid body can be replaced by a single force equal to \mathbf{R}^i and applied at the centre O, and a couple of moment \mathbf{M}_O^i . The principal vector of a system, it will be recalled, does not depend on the centre of reduction and can be computed at once. As $\mathbf{F}_k^i = -m_k \mathbf{w}_k$, then taking into account Eq. (15) (§ 135), we will have: **

$$\mathbf{R}^i = -\sum m_k \mathbf{w}_k = -\mathcal{M} \mathbf{w}_C. \quad (61)$$

Thus, the *principal vector of the inertia forces of a moving body is equal to the product of the mass of the body and the acceleration of its centre of mass, and is opposite in direction to the acceleration.*

* This follows from the reasoning in § 3 when the principle of solidification was examined. See also the remarks on the general theorems of dynamics in § 134.

** To avoid confusion between the symbols for mass and moment, in this chapter we shall denote mass by the symbol \mathcal{M} (see footnote on p. 309).

If we resolve the acceleration ω_c into its tangential and normal components, then vector R^i will resolve into components

$$R_t^i = m \omega_{ct}, \quad R_n^i = m \omega_{cn}. \quad (61')$$

Let us determine the principal moment of the inertia forces for particular types of motion.

1. **Translatory Motion.** In this case a body has no rotation about its centre of mass C , from which we conclude that $\sum m_c (F_k^{ext}) = 0$, and Eq. (60) gives $M_C^i = 0$.

Thus, in translatory motion, the inertia forces of a rigid body can be reduced to a single resultant R^i through the centre of mass of the body.

2. **Plane Motion.** Let a body have a plane of symmetry, and let it be moving parallel to the plane. By virtue of symmetry, the principal vector and the resultant couple of inertia forces lie, together with the centre of mass C , in that plane.

Therefore, placing the centre of reduction in point C , we obtain from Eq. (60) $M_C^i = -\sum m_c (F_k^{ext})$. On the other hand (see § 156), from the last of Eqs. (52), $\sum m_c (F_k^{ext}) = J_C \epsilon$. We conclude from this that

$$M_C^i = -J_C \epsilon. \quad (62)$$

Thus, in such motion a system of inertia forces can be reduced to a resultant force R^i [Eq. (61)] applied at the centre of mass C (Fig. 348) and a couple in the plane of symmetry of the body whose moment is given by Eq. (62). The minus sign shows that the moment M_C^i is in the opposite direction of the angular acceleration of the body.

3. **Rotation about an Axis Through the Centre of Mass.** Let a body have a plane of symmetry, and let the axis of rotation Cz be normal to the plane through the centre of mass. This case will thus be a particular case of the previous motion. But here $\omega_c = 0$, and consequently, $R^i = 0$.

Thus, in this case a system of inertia forces can be reduced to a couple in the plane of symmetry of the body of moment

$$M_z^i = -J_z \epsilon. \quad (62')$$

In applying Eqs. (61) and (62) to problem solutions, the magnitudes of the respective quantities are computed and the directions are shown in a diagram.

Fig. 348.

160. Solution of Problems. D'Alembert's principle supplies a uniform method for developing the equations of motion of any constrained system*. It provides simple, graphic solutions of problems where we have to determine the reactions of constraints when the motion of a system is known. In these solutions all the immediately unknown internal forces are excluded from consideration. When we have to determine the reactions of internal constraints, the system is divided into parts so that the required forces would be external.

D'Alembert's principle is also conveniently used to develop the differential equations of motion and, in particular, to determine the acceleration of moving bodies.

Problem 149. Two weights P_1 and P_2 are connected by a thread and move along a horizontal plane under the action of a force Q applied to the first weight (Fig. 349a). The coefficient of friction of the weights on the plane is f . Determine the accelerations of the weights and the tension in the thread.

Fig. 349.

Solution. Denote all the external forces acting on the system and add to them the inertia forces of the weights. As both weights are translated with the same acceleration w , then in magnitude

$$F_1^i = \frac{P_1}{g} w \text{ and } F_2^i = \frac{P_2}{g} w.$$

The forces are directed as shown. The frictional forces are

$$F_1 = fP_1, \quad F_2 = fP_2.$$

According to D'Alembert's principle, the force system must be in equilibrium. Writing the equilibrium equation in terms of the projections on axis Ox , we find

$$Q - f(P_1 + P_2) - \frac{1}{g}(P_1 + P_2)w = 0,$$

whence

$$w = \left(\frac{Q}{P_1 + P_2} - f \right) g.$$

Evidently, the weights will move if $f < \frac{Q}{P_1 + P_2}$.

In our force system the required tension in the thread is an internal force. To determine it we divide the system and apply D'Alembert's principle to one

* D'Alembert's principle is especially effective when used in combination with the principle of virtual work (see § 167).

of the weights, say the second (Fig. 349b). Acting on it is force P_2 , the normal reaction N_2 , the frictional force F_2 , and the tension T in the thread. Add to them the inertia force F_2^i and write the equilibrium equation in terms of the projections on axis Ox . We have

$$T - \{P_2 - \frac{P_2}{g} \omega = 0.$$

Substituting the earlier found value of ω , we obtain finally

$$T = \frac{QP_2}{P_1 + P_2}.$$

It is interesting to note that the tension in the thread does not depend on the friction and, given the same total weight of the system, it decreases with the reduction of the second (rear) weight. That is why, for example, in making up a goods train it is better to place the heavier vans closer to the locomotive.

Assigning specific values to the quantities of this problem, let $Q = 20$ kg, $P_1 = 40$ kg, and $P_2 = 10$ kg. Then motion is possible when $f < 0.4$ and the tension in the thread is 4 kg. If the weights are reversed, the tension in the thread will be 16 kg.

Problem 150. Solve Problem 133 (p. 338) with the help of D'Alembert's principle and also determine the tension in the thread.

Solution. 1) Considering the drum and the load as a single system, we add to the bodies of the system inertia forces (Fig. 350). Load A is in trans-

Fig. 350.

latory motion, and for it $R^i = \frac{Q}{g} \omega_A = \frac{Q}{g} r\epsilon$. The inertia forces of the drum can be reduced to a couple of moment M_O^i equal in magnitude to $J_O\epsilon = \frac{P}{g} r^2\epsilon$ and directed opposite the rotation (see § 159). Writing now for all the forces the equilibrium conditions in the form $\sum m_O(F_k) = 0$, we obtain

$$|M_O^i| + R^i r - Qr = 0,$$

or

$$\frac{P}{g} r^2 \epsilon + \frac{Q}{g} r^2 \epsilon - Qr = 0,$$

from which we find

$$\epsilon = \frac{Qgr}{PQr^2 + Qr^2}.$$

2) Considering now load A separately and adding to the active forces Q and T the inertia force R^i , we obtain from the equilibrium conditions that the tension in the thread

$$T = Q - R^i = Q \left(1 - \frac{r\epsilon}{g} \right) = \frac{PQr^2}{PQr^2 + Qr^2}.$$

Problem 151. Determine the forces acting on a spinning flywheel, assuming its mass to be distributed along the rim. The weight of the flywheel is P , its radius r , and its angular velocity ω .

Writing now the statics equation $\sum m_A(F_k) = 0$, we obtain

$$Tl \cos \alpha - R^i h - P \frac{l}{2} \sin \alpha = 0.$$

Substituting the values of R^i and h into this equation, we obtain finally

$$T = P \left(\frac{l\omega^2}{3g} \sin \alpha + \frac{1}{2} \tan \alpha \right).$$

Alternate Solution. The problem can be solved without applying the conclusions of § 28, by directly computing the sum of the moments of the inertia forces with respect to centre A by integration. Draw along rod AB an axis $A\xi$. Acting on each element $d\xi$ of the rod, whose co-ordinate is ξ , there is an inertia force equal to $\omega^2 x dm$. Its moment with respect to A is $y\omega^2 x dm$. Then the equation of moments gives

$$\sum m_A(F_k) = Tl \cos \alpha - P \frac{l}{2} \sin \alpha - \int_0^l \omega^2 y x dm = 0. \quad (a)$$

Expressing all the quantities under the integration sign in terms of ξ , we obtain

$$x = \xi \sin \alpha, \quad y = \xi \cos \alpha, \quad dm = \frac{\rho}{l} d\xi,$$

from which we have

$$\int_0^l \omega^2 y x dm = \frac{\rho}{l} \omega^2 \sin \alpha \cos \alpha \int_0^l \xi^2 d\xi = \frac{1}{3} \frac{P}{g} l^2 \omega^2 \sin \alpha \cos \alpha.$$

Substituting this expression into equation (a), we obtain for T the same expression as in the first solution.

Problem 153. A homogeneous rod AB of mass ρ and length l rotates about an axis perpendicular to it with an angular velocity ω and an angular acceleration ϵ (Fig. 353a). Determine the stresses generated by the rotation in a cross section of the rod at a distance x from the axis.

Solution. The required forces are internal. To determine them, cut the rod into two and consider the motion of portion DB of length $a = l - x$ (Fig. 353b). The action of the removed portion AD is replaced by a force applied at the centre D of the cross section, which we shall represent by its components P and Q , and a couple of moment M_D (see § 26, Fig. 62). The quantities P , Q , and M_D will specify the required stresses in section D of the rod, i.e., the forces with which portions AD and DB act on one another. To compute these quantities we use D'Alembert's principle. First let us find the principal vector R^i of the inertia forces of portion DB , and their principal moment M_C^i with respect to the centre of mass C of the portion. The mass m of

Fig. 353.

portion DB and the coordinate $x_C = AC$ of its centre of mass are, evidently,

$$m = \frac{l-x}{l} \mathcal{M}, \quad x_C = \frac{l+x}{2}.$$

Then, from Eqs. (61'), we find the magnitudes of vectors R_z^i and R_n^i :

$$|R_z^i| = m |\omega_{Cz}| = mx_C |\epsilon| = \mathcal{M} |\epsilon| \frac{l^2 - x^2}{2l},$$

$$R_n^i = m \omega_{Cn} = mx_C \omega^2 = \mathcal{M} \omega^2 \frac{l^2 - x^2}{2l}.$$

Furthermore, from Eq. (62), $M_C^i = -J_C \epsilon$. As in this case (see Problem 122 on p. 315) $J_C = \frac{ma^2}{12}$, then

$$|M_C^i| = \mathcal{M} \frac{(l-x)^2}{12l} |\epsilon|.$$

The forces R_z^i and R_n^i and the moment M_C^i are directed as shown in the diagram.

Thus, all the inertia forces of portion DB of the rod are replaced by a force R^i applied at C , whose components are R_z^i and R_n^i , and a couple of moment M_C^i . Writing now the equilibrium conditions $\sum F_{kx} = 0$, $\sum F_{ky} = 0$, $\sum m_D (F_k) = 0$ for the active forces and the inertia forces applied to portion DB , we obtain

$$R_n^i - P = 0; \quad Q - |R_z^i| = 0; \quad M_D - |M_C^i| - |R_z^i| \frac{a}{2} = 0.$$

From this we find finally that acting at section D of the rod are 1) a tensile force $P = R_n^i$, 2) a transverse force $Q = |R_z^i|$, and 3) a couple with a bending moment

$$M_D = |M_C^i| + |R_z^i| \frac{a}{2} = \frac{\mathcal{M} |\epsilon|}{12l} [(l-x)^2 + 3(l+x)(l-x)^2],$$

or finally

$$M_D = \frac{\mathcal{M} |\epsilon|}{6l} (l-x)^2 (2l+x).$$

The value of forces P , Q and the bending moment will be greatest, it will readily be noticed, at the cross section $x=0$.

161. Dynamical Pressures on the Axis of a Rotating Body. Consider a rigid body rotating *uniformly* with an angular velocity about an axle mounted in bearings A and B (Fig. 354). Let us find the *dynamical pressures* $X_A^D, Y_A^D, Z_A^D, X_B^D, Y_B^D$ exerted by the bearings on the axle, i.e., the pressures due *only* to the rotation of the body. Applying D'Alembert's principle, we add to the required forces the principal vector and the principal moment of the inertia forces and write the equilibrium equations (60) in

terms of the projections on the coordinate axes, which rotate together with the body. In our case these equations (or the corresponding equations of § 48) take the form (denoting $AB = b$):

$$\left. \begin{aligned} X_A^D + X_B^D + R_x^i &= 0, \\ Y_A^D + Y_B^D + R_y^i &= 0, \quad Z_A^D + R_z^i = 0, \\ -Y_B^D b + M_x^i &= 0, \quad X_B^D b + M_y^i = 0. \end{aligned} \right\} \quad (63)$$

The last equation $M_z^i = 0$ is an identity and we omit it.

The principal vector of the inertia forces $R^i = -\omega \omega_C$. At $\omega = \text{const.}$, the centre of mass C has only a normal acceleration $\omega_{Cn} = h_C \omega^2$, where h_C is the distance of point C from the axis of rotation.

Consequently, vector R^i is directed along OC and *

$$\begin{aligned} R_x^i &= \omega \omega^2 h_C \cos \alpha = \omega^2 x_C, \\ R_y^i &= \omega \omega^2 h_C \sin \alpha = \omega^2 y_C, \\ R_z^i &= 0, \end{aligned}$$

where x_C and y_C are the co-ordinates of the centre of mass.

In order to determine M_x^i and M_y^i , consider any particle of the body of mass m_k located at a distance h_k from the axle. For this particle, at $\omega = \text{const.}$, the inertia force has only a centrifugal component $F_k^i = m_k \omega^2 h_k$, the projections of which, like the projections of R^i , are

$$F_{kx}^i = m_k \omega^2 x_k, \quad F_{ky}^i = m_k \omega^2 y_k, \quad F_{kz}^i = 0.$$

Then [see § 42, Eqs. (52)]

$$\begin{aligned} m_x(F_k^i) &= -F_{ky}^i z_k = -m_k \omega^2 y_k z_k, \\ m_y(F_k^i) &= F_{kx}^i z_k = m_k \omega^2 x_k z_k. \end{aligned}$$

Writing similar expressions for all the particles of the system, adding them, and taking the common multiplier ω^2 outside the

* Vector R^i in the diagram is the *principal vector* of the inertia forces, not their *resultant*. Reduced to centres C or O , the inertia forces will give also a couple.

Fig. 354.

parentheses, we obtain

$$M'_x = -(\sum m_k y_k z_k) \omega^2 = -J_{yz} \omega^2, \quad M'_y = (\sum m_k x_k z_k) \omega^2 = J_{xz} \omega^2. \quad (64)$$

The quantities

$$J_{xz} = \sum m_k x_k z_k, \quad J_{yz} = \sum m_k y_k z_k \quad (65)$$

in Eq. (64) are called the *products of inertia*. It will be noticed from Eqs. (65) that, like the moment of inertia with respect to an axis, the product of inertia depends only on the distribution of mass in a body. The physical interpretation of the concept will be explained further on.

Substituting all the obtained quantities into Eqs. (63) and omitting all quantities equal to zero, we have

$$\left. \begin{aligned} X_A^D + X_B^D &= -m x_C \omega^2, & Y_A^D + Y_B^D &= -m y_C \omega^2; \\ X_B^D b &= -J_{xz} \omega^2, & Y_B^D b &= -J_{yz} \omega^2. \end{aligned} \right\} \quad (66)$$

Equations (66) specify the dynamical pressures acting on the axle of a uniformly rotating rigid body, when axis Oz is taken coincident with the axle.

If there will be acting on the body any forces F_k^{ext} [satisfying, of course, the condition $\sum m_i (F_i^{ext}) = 0$], they will produce additional static pressures defined by Eqs. (66) (§ 48), i.e., as if the body were at rest. The total action on the axle, then, will be equal to the sum of the dynamical and static pressures.

162. The Principal Axes of Inertia of a Body. Dynamic Balancing of Masses. The appearance of dynamical pressures acting on an axle depends on the manner in which the mass of a body is distributed with respect to the axle. The presence of these pressures is an indication of the *dynamic unbalance* of the masses.

Equations (66) suggest that, to eliminate dynamic unbalance, we must, first of all, have

$$x_C = 0, \quad y_C = 0 \quad (67)$$

i.e., the axis of rotation should pass through the centre of mass of a body. In this case $X_A^D = -X_B^D$, and $Y_A^D = -Y_B^D$, i.e., the dynamical pressures will not disappear, but will make a couple which will rotate together with the body and cause the axle to vibrate*.

* Such vibrations, besides increasing the wear and tear of the bearings, may induce resonance in the parts or bedding of a machine (§ 126), which is very undesirable.

Thus the dynamic balance (or unbalance) of a body depends not only on the position of the centre of mass but on the products of inertia J_{xz} and J_{yz} as well. This leads us to the physical interpretation of the concept: *the products of inertia J_{xz} and J_{yz} are a measure of the degree of dynamic unbalance of a body rotating about an axis Oz .*

For perfect dynamic balance the additional conditions

$$J_{xz} = 0, \quad J_{yz} = 0 \quad (68)$$

must be satisfied.

Axis Oz , with respect to which the products of inertia J_{xz} and J_{yz} are zero, is called *the principal axis of inertia of the body with respect to point O* . For example, if plane Oxy is the body's plane of material symmetry, then Oz will be the principal axis of inertia with respect to point O , insofar as to any particle with coordinates x, y, z there is a symmetrically located particle with coordinates $x, y, -z$, and, consequently, the summations in Eqs. (65) will vanish. Similarly, Ox will be the principal axis with respect to O , if $J_{yx} = J_{zx} = 0$, etc.

The principal axis of inertia through the centre of mass of a body is called *the principal central axis of inertia*. Thus, if the Oz axis is the body's axis of material symmetry, then it will be the body's principal central axis of inertia, insofar as to any particle with coordinates x, y, z , there is a symmetrically located particle with coordinates $-x, -y, z$, and, consequently, the summations (65) will vanish. That simultaneously $x_c = y_c = 0$ is known from statics.

It follows from the above considerations that the *dynamical pressures acting on the axle of a rotating body will be zero if the axle coincides with the principal central axis of inertia of the body* (for instance, with the axis of material symmetry). This conclusion is also valid for a non-uniformly rotating body.

The dynamic balancing of masses is an important engineering problem which, we have seen, involves the determination of the principal central axes of inertia of a body.

It should not be assumed that only symmetrical bodies possess principal axes. It can be proved that there pass through any point, including the centre of mass, of any non-symmetrical body three mutually perpendicular axes of inertia which are principal axes with respect to the given point.

Let us prove another statement which is no less important in practice: *any axis passing through a body can be made a principal central axis of inertia by adding two point masses to the body*. Let us have a body of mass m , and let the quantities $x_c, y_c,$

J_{xz} and J_{yz} be known and not equal to zero. Let us further add to the body two masses m_1 and m_2 at points whose coordinates are x_1, y_1, z_1 and x_2, y_2, z_2 . Then, from Eqs. (4) and (65), it follows that if

$$\left. \begin{aligned} mx_C + m_1x_1 + m_2x_2 &= 0, & J_{xz} + m_1x_1z_1 + m_2x_2z_2 &= 0, \\ my_C + m_1y_1 + m_2y_2 &= 0, & J_{yz} + m_1y_1z_1 + m_2y_2z_2 &= 0, \end{aligned} \right\} \quad (69)$$

then for the resulting body we shall have $x'_C = y'_C = J'_{xz} = J'_{yz} = 0$, i.e., the Oz axis will be the principal central axis of inertia. The problem is solved by choosing the masses m_1 and m_2 and their positions such that Eqs. (69) will be satisfied. Some of the quantities, of course, must be specified in advance. For instance, we may specify the values of m_1, m_2 and z_1, z_2 (but such that $z_1 \neq z_2$) and find x_1, y_1, x_2, y_2 from Eqs. (69), etc.

This method is widely used in engineering for balancing crankshafts, cranks, coupling rods, etc. Final balancing is done on special balancing machines.

When it is necessary to determine the pressures acting on an axle, the ready equations (66) are usually not used, and D'Alembert's principle is applied for each specific case. All the forces acting on the body are generally considered and the *total* pressures are found, i.e., the sum of the static and dynamical pressures on the axis.

Fig. 355.

bert's principle is applied for each specific case. All the forces acting on the body are generally considered and the *total* pressures are found, i.e., the sum of the static and dynamical pressures on the axis.

Problem 154. The axis of rotation of a disc is perpendicular to the plane of the disc and passes at a distance a from the centre of mass (Fig. 355). The disc weighs P and its angular velocity is ω . Determine the dynamical pressures acting on the axle if $OA = OB$.

Solution. The Oz axis is the principal axis of inertia with respect to point O , since plane Oxy is the plane of symmetry of the disc. Then, $J_{xz} = J_{yz} = 0$, and, from Eqs. (64), $M_O^i = 0$, i.e., the inertia forces are reduced to a single resultant through point O along OC (the Oy axis). In magnitude $R^i = m\omega^2 r = \frac{P}{g} a\omega^2$, and it will be readily noticed that

$$Y_A^D = Y_B^D = \frac{Pa\omega^2}{2g}.$$

Forces Y_A^D and Y_B^D remain continually in plane Oyz , which rotates together with the body.

In addition to these pressures, there act the static pressures due to the force of gravity P , which can be calculated if the distance AB is known.

Problem 155. Two equal bars of length l and weight p each are welded at right angles to a vertical shaft AB of length b at a distance h from each other (Fig. 356). Determine the dynamical pressures acting on the shaft if it rotates with a constant angular velocity ω .

Solution. The centrifugal inertia forces in each rod are equal in magnitude:

$$F_1^i = F_2^i = \frac{p}{g} \frac{l}{2} \omega^2,$$

and they make a couple which, apparently, is balanced by the couple X_A^D, X_B^D . The moments of these couples are equal in magnitude. Consequently, $X_A^D b = F_1^i h$, whence

$$X_A^D = X_B^D = \frac{F_1^i h}{b} = \frac{plh}{2gb} \omega^2.$$

The couple is continuously in the Axz plane, which rotates with the body.

Let us show that the same result can be obtained from Eqs. (66). In our case, $x_C = y_C = 0$, and $J_{yz} = 0$, as the plane Axz is the plane of symmetry. The quantity $J_{xz} = J'_{zx} + J''_{xz}$, i.e., it is equal to the sum of the products of inertia of each bar. For the lower bar, all $z_k = a$, and for the upper one all $z_k = a + h$. Then from Eq. (65),

$$J'_{xz} = \left(\sum m_k x_k \right) a = m x'_C a = -\frac{p}{g} \frac{l}{2} a, \quad J''_{xz} = m x''_C (a + h) = \frac{p}{g} \frac{l}{2} (a + h),$$

whence

$$J_{xz} = \frac{p}{g} \frac{l}{2} h.$$

Substituting all the expressions into Eqs. (66), we find

$$Y_A^D = Y_B^D = 0,$$

$$X_A^D = -X_B^D = \frac{plh}{2gb} \omega^2.$$

The reason for the minus sign at X_B^D is that the forces X_B^D in Figs 354 and 356 are of opposite sense.

Problem 156. The crankshaft of a one-cylinder gas engine carries two identical flywheels A and B of radius $r = 0.5$ m as shown in Fig. 357. The crank arms and crankpin are equivalent to a weight of $p = 21$ kg at a distance of $h = 0.2$ m from the axis. If $a = 0.6$ m and $b = 1.4$ m, what correction weights p_A and p_B placed on the rims of the flywheels will balance the system?

Solution. Draw a set of coordinate axes rotating with the body, such that the crankpin would lie in the Oxz plane. This plane, then, will be the plane of symmetry, and, consequently, $y_C = 0$ and, as Oy is a principal axis with respect to point O , $J_{yz} = 0$. Furthermore, introducing the notation P for

Fig. 356.

Fig. 357.

the total weight of the system, we have

$$x_C = \frac{ph}{P}, \quad J_{xz} = \frac{P}{g} ha.$$

The latter equality follows from the fact that the product of inertia of a system equals the sum of the products of inertia of its components, and the products of inertia J_{xz} of the flywheels and adjacent sections of the crankshaft are zero (Oz is the axis of symmetry).

The coordinates of the correction weights, from Eqs. (69), are $y_A = y_B = 0$, and the weights themselves must satisfy the equations

$$Px_C + p_A x_A + p_B x_B = 0, \quad J_{xz} + \frac{p_A}{g} x_A z_A + \frac{p_B}{g} x_B z_B = 0.$$

As the weights are to be placed on the rims of the flywheels, $z_A = 0$, $z_B = b$, and $x_A = x_B = -r$ (the equations have no solutions when the sign is positive, therefore the weights must be at the bottom). Solving the equations, we find

$$p_A = \frac{(b-a)h}{rb} p = 4.8 \text{ kg}, \quad p_B = \frac{ah}{rb} p = 3.6 \text{ kg}.$$

Addition of these weights balances the system and makes Oz the principal central axis of inertia (but not the axis of symmetry).

Chapter 30

THE PRINCIPLE OF VIRTUAL WORK AND THE GENERAL EQUATION OF DYNAMICS

163. Virtual Displacements of a System. Degrees of Freedom. In the first part of our course we studied the methods of so-called graphical statics. In determining the equilibrium conditions of a system by these methods we had to consider the equilibrium of every body separately, replacing the action of all applied constraints by the unknown reaction forces. When the number of bodies in a system is large, this method becomes cumbersome, involving the solution of a large number of equations with many unknown quantities.

Now we shall make use of a number of kinematical and dynamical concepts to investigate a more general method for the solution of problems of statics which makes it possible to determine at once the equilibrium conditions for any mechanical system. The basic difference between this method and the methods of geometrical statics is that the action of constraints is taken into account not by introducing the reaction forces but by investigating the possible displacements of a system if its equilibrium were disturbed. These displacements are known in mechanics by the name of *virtual displacements*.

Virtual displacements of the particles of a system must satisfy two conditions: 1) they must be infinitesimal, since if a displacement is finite the system will occupy a new configuration in which the equilibrium conditions may be different; 2) they must be *consistent with the constraints of the system*, as otherwise we should change the character of the mechanical system under consideration.

For instance, in the crankshaft mechanism in Fig. 358, a displacement of the points of the crank OA into configuration OA_1 cannot be considered as a virtual displacement, as the equilibrium conditions under the action of forces P and Q will have changed. At the same time, even an infinitesimal displacement of point B of the connecting rod along BD would not be a virtual displacement: it would have been possible if the slides at B were replaced by a rocker (see Fig. 188, where C is a rocker), i.e., if it were a different mechanism.

Fig. 358.

Thus, we shall define as a *virtual displacement of a system* the sum total of any arbitrary infinitesimal displacements of the particles of the system consistent with all the constraints acting on the system at the given instant. We shall denote the virtual displacement of any point by an elementary vector δs in the direction of the displacement.

In the most general case, the particles and bodies of a system may have a number of different virtual displacements (not considering δs and $-\delta s$ as being different). For every system, however, depending on the type of constraints, we can specify a certain number of independent virtual displacements such that any other virtual displacements will be obtained as their geometrical sum. For example, a bead lying on a horizontal plane can move in many directions on the plane. Nevertheless, any virtual displacement δs may be produced as the sum of two displacements δs_1 and δs_2 along two mutual perpendicular horizontal axes ($\delta s = \delta s_1 + \delta s_2$).

The number of possible mutually independent displacements of a system is called the *number of degrees of freedom of that system*. Thus, a bead on a plane (regarded as a particle) has two degrees of freedom. A crankshaft mechanism, evidently, has one degree of freedom. A free particle has three degrees of freedom (three independent displacements along mutually perpendicular axes). A free rigid body has six degrees of freedom (three translatory displacements along orthogonal axes and three rotations about those axes).

164. Ideal Constraints. If a particle has for a constraint a smooth surface or curve, the reaction \mathbf{N} of the constraint is normal to the surface (or curve), and the elementary work done by the force \mathbf{N} in any virtual displacement of the particle is zero (see § 114). It was shown in § 149 that if we neglect rolling friction, the sum of the work done by the reaction forces \mathbf{N} and \mathbf{F}_{fr} in any virtual displacement of a rolling body is also zero. The internal forces of any non-deformable system also possess this property (§ 148, Fig. 320).

Consider another example. Neglecting friction in the axles and along the slides of the crankshaft mechanism in Fig. 358, the work done by reaction \mathbf{N}_O is zero, as point O has no displacement, the work done by force \mathbf{N}_B is zero because \mathbf{N}_B is perpendicular to the possible displacement of point B . The work done by each of the reactions \mathbf{N}_A and \mathbf{N}'_A (\mathbf{N}_A is the force with which the connecting rod acts on the crank, and \mathbf{N}'_A is the pressure of the crank on the connecting rod) is not separately zero, but the sum is zero, as $\mathbf{N}_A = -\mathbf{N}'_A$ and they are applied at the same point.

Let us introduce the following notation: the elementary work done by an active force \mathbf{F}^a in any virtual displacement $\delta\mathbf{s}$ —the virtual work—shall be denoted by the symbol δA^a ($\delta A^a = F^a \delta s \cos \alpha$, where α is the angle between the directions of the force and the displacement), and the virtual work done by the reaction \mathbf{N} of a constraint, by the symbol δA^N . Then for all the constraints considered here,

$$\sum \delta A_k^N = 0. \quad (70)$$

Constraints in which the sum of the virtual work produced by all the reaction forces in any virtual displacement of a system is zero are called *ideal constraints*.

We have seen that to such constraints belong all frictionless constraints along which a body slides and all rough constraints when a body rolls along them, neglecting rolling friction.

165. The Principle of Virtual Work. Consider a system of material particles in equilibrium under the action of the applied forces and constraints, assuming all the constraints imposed on the system to be ideal. Let us take an arbitrary particle B_k belonging to the system and denote the resultant of all the applied active forces (both external and internal) by the symbol \mathbf{F}_k^a , and the resultant of all the reactions of the constraints (also external and internal) by the symbol \mathbf{N}_k . Then, since point B_k is in equilibrium together with the system, $\mathbf{F}_k^a + \mathbf{N}_k = 0$, or $\mathbf{N}_k = -\mathbf{F}_k^a$.

Consequently, in any virtual displacement of point B_k , the virtual work δA_k^a and δA_k^N done by the forces F_k^a and N_k are equal in magnitude and opposite in sense and therefore vanish*, i.e., we have.

$$\delta A_k^a + \delta A_k^N = 0.$$

Reasoning in the same way we obtain similar equations for all the particles of a system, adding which we obtain

$$\sum \delta A_k^a + \sum \delta A_k^N = 0.$$

But from the property of ideal constraints (70), the second summation is zero, whence

$$\sum \delta A_k^a = 0, \quad (71)$$

or

$$\sum (F_k^a \delta s_k \cos \alpha_k) = 0. \quad (71')$$

We have thus proved that if a mechanical system with ideal constraints is in equilibrium, the active forces applied to it satisfy the condition (71). The reverse is also true, i.e., if the active forces satisfy the condition (71), the system is in equilibrium. From this follows the principle of virtual work**: *the necessary and sufficient conditions for the equilibrium of a system subjected to ideal constraints is that the total virtual work done by all the active forces is equal to zero for any and all virtual displacements consistent with the constraints.* Mathematically the necessary and sufficient condition for the equilibrium of any mechanical system is expressed by Eq. (71).

In analytical form this condition can be expressed as follows (see § 112):

$$\sum (F_{kx}^a \delta x_k + F_{ky}^a \delta y_k + F_{kz}^a \delta z_k) = 0. \quad (72)$$

In Eq. (72) δx_k , δy_k , δz_k are the projections of the virtual displacements δs_k of point B_k on the coordinate axes. They are equal to the infinitesimal increments to the position coordinates

* Point B_k is at rest and has no displacement. Here we are considering what the work done by the acting forces would be for any virtual displacement of point B_k .

** This principle was formulated very like the present definition, but without proof, by the celebrated Swiss mathematician and mechanic John Bernoulli (1667-1748). In general form the principle was enunciated and proved by Lagrange, in 1788. The principle was generalised for the case of unilateral constraints (constraints from which a body can escape) by M. V. Ostrogradsky in his works of 1838-1842.

of the point in its displacement and are computed in the same way as the differentials of coordinates.

The principle of virtual work provides in general form the equilibrium conditions of any mechanical system, whereas the methods of geometrical statics require the consideration of the equilibrium of every body of the system separately. Furthermore, application of the principle of virtual work requires that only the active forces be considered and makes it possible to ignore all the unknown reactions of constraints, when the constraints are ideal.

166. Solution of Problems. For a system with one degree of freedom, Eqs. (71) and (72) immediately give the equilibrium conditions. If a system has several degrees of freedom, then the conditions (71) or (72) must be developed *for each of the independent displacements of the system separately*, i.e., the number of equilibrium equations is equal to the number of degrees of freedom of a system.

In problem solutions the number of degrees of freedom of plane mechanisms is conveniently determined as follows. Imagine a mechanism to be moving. If by stopping a translation or rotation of any unit we stop the whole mechanism, then it has one degree of freedom. If, when the translation or rotation of any unit is stopped, the mechanism continues to move, and if it can be stopped by additionally preventing the displacement of some other part, then it has two degrees of freedom, etc.

For solving problems by the *geometrical method* we must: 1) draw all the *active* forces applied to the system under consideration; 2) impart a virtual displacement to the system and denote by vectors δs_k the elementary displacements of the points of application of the forces, or by angles $\delta \varphi_k$ the elementary rotations of the bodies subjected to forces (if a system has several degrees of freedom, it must be given one of the independent displacements); 3) compute the virtual work done by all the active forces in the given displacement according to the formulas

$$\delta A_k^a = F_k^a \delta s_k \quad \text{or} \quad \delta A_k^a = m_o (F_k^a) \delta \varphi_k$$

and write condition (71); 4) establish the dependence between the quantities δs_k and $\delta \varphi_k$ in Eq. (71) and express all of them in terms of one quantity (as the system was given an *independent* displacement, there must always exist a relationship between the displacements δs_k and $\delta \varphi_k$, which can be found).

When all the quantities δs_k or $\delta \varphi_k$ in Eq. (71) are expressed in terms of one of them, we obtain an equation from which we can find the required quantity or relation.

When a system has several degrees of freedom, the foregoing procedure must be repeated for each independent displacement.

The relation between the quantities δs_k and $\delta \varphi_k$ can be found either: a) from purely geometrical considerations (Problems 157 and 162), or b) kinematically: first determine the relation between the corresponding linear velocity v_k and angular velocity ω_k which the system would have if it were in motion and then take into account that $\delta s_k = v_k dt$ and $\delta \varphi_k = \omega_k dt$ (Problems 158, 159 and others).

The *analytical method* is usually employed when the simpler way is inadequate to determine the dependence between δs_k and $\delta \varphi_k$. The equilibrium equation is written in the form (72). For this a set of coordinate axes must be chosen and the projections of all the active forces on these axes and the position coordinates x_k, y_k, z_k of all the points of application of the forces must be computed, the coordinates being expressed in terms of any one parameter (angle, for instance). Then the quantities $\delta x_k, \delta y_k, \delta z_k$ are found by differentiating the coordinates x_k, y_k, z_k with respect to that parameter.

If it is impossible to express all the coordinates x_k, y_k, z_k in terms of one parameter immediately, several parameters should be introduced, such that the relation between them can later be established.

In conclusion, note that conditions (71) and (72) can be applied when there are frictional forces, if they are included among the active forces. Similarly, the reactions of constraints can be determined if the corresponding constraints are removed and their reactions are included among the active forces.

Problem 157. Find the relation between forces P and Q in the mechanism shown in Fig. 359 if it is in equilibrium.

Solution. If we give the system a virtual displacement, the diagonals of all the parallelograms formed by the rods will receive the same increment δs . We have $\delta s_A = \delta s$, and $\delta s_B = 3\delta s$. Writing condition (71), we obtain

$$P\delta s_B - Q\delta s_A = 0 \quad \text{or} \quad (3P - Q)\delta s = 0,$$

whence $Q = 3P$. The solution, we see, is very simple.

Problem 158. A beam of weight Q is supported on two cylindrical rollers of weight P each. What force F must be applied to the beam to maintain equilibrium on a plane making an angle α with the horizontal if there is no slipping between either the rollers and the inclined plane or the rollers and the beam (Fig. 360).

Solution. If we neglect rolling friction, the plane will be an ideal constraint for both rollers. If a virtual displacement is given to the system, we obtain from condition (71)

$$F\delta s_B - Q \sin \alpha \delta s_B - 2P \sin \alpha \delta s_C = 0,$$

Fig. 359.

where δs_B is the virtual displacement of the point of the beam coincident with point B . The point of contact K is the instantaneous centre of zero velocity of the roller, therefore $v_B = 2v_C$ and $\delta s_B = 2\delta s_C$, since $\delta s_B = v_B dt$, and $\delta s_C = v_C dt$. Substituting this expression for δs_B into the foregoing equation, we obtain finally

$$F = (Q + P) \sin \alpha.$$

Problem 159. Find the relation between the moment M of the couple acting on the crankshaft mechanism in Fig. 361 and the pressure P on the piston when the system is in equilibrium. The crank is of length $OA = r$ and the connecting rod is of length $AB = l$.

Fig. 360.

Fig. 361.

Solution. Equilibrium conditions (71) give

$$M\delta\varphi - P\delta s_B = 0 \quad \text{or} \quad M\omega_{OA} = Pv_B,$$

since $\delta\varphi = \omega_{OA}dt$, and $\delta s_B = v_B dt$. The solution requires that the relation be found between v_B and ω_{OA} . This kinematic problem was solved in Problem 71, § 82. Referring to the result obtained there, we find

$$M = Pr \left(1 + \frac{r \cos \varphi}{\sqrt{l^2 - r^2 \sin^2 \varphi}} \right) \sin \varphi.$$

Problem 160. For the reduction gear considered in Problem 91, § 96, find the relation between the torque M_A applied to the driving shaft A and the resistance moment M_B applied to the driven shaft B when both shafts are rotating uniformly.

Solution. The relation between M_A and M_B will be the same in uniform rotation as in equilibrium. Therefore, from Eq. (71) we have

$$M_A\delta\varphi_A - M_B\delta\varphi_B = 0 \quad \text{or} \quad M_A\omega_A = M_B\omega_B,$$

as $\delta\varphi_A = \omega_A dt$, and $\delta\varphi_B = \omega_B dt$. Hence, referring to the result obtained in Problem 91, we find

$$M_A = \frac{\omega_B}{\omega_A} M_B = \frac{n_B}{n_A} = 2.8M_B.$$

Fig. 362.

Problem 161. Find the relation between forces P and Q in the hoisting mechanism in Fig. 362, whose parts are housed in the box K , if it is known that in one revolution of the crank handle $AB = l$ the screw D moves out by h .

Solution. From Eq. (71) we have

$$Pl\delta\varphi_{AB} - Q\delta s_D = 0.$$

Assuming that when the handle is rotated uniformly the screw also moves up uniformly, we have

$$\frac{\delta\varphi_{AB}}{2\pi} = \frac{\delta s_D}{h} \quad \text{or} \quad \delta\varphi_{AB} = \frac{2\pi}{h} \delta s_D.$$

Substituting this expression for $\delta\varphi_{AB}$ into the foregoing equation, we obtain

$$Q = \frac{2\pi l}{h} P.$$

Note that this simple problem could just not be solved by the methods of geometrical statics as the parts of the mechanism are unknown.

Problem 162. Two beams are hinged together at C and loaded as shown in Fig. 363a. Neglecting the weight of the beams, determine the pressure on support B .

Solution. Replace the support at B by a force N_B , which is equal in magnitude to the required pressure (Fig. 363b). For a virtual displacement of the system Eq. (71) gives

$$N_B \delta s_B - P \delta s_E = 0.$$

The relation between δs_B and δs_E is found from the proportions

$$\frac{\delta s_B}{a} = \frac{\delta s_C}{l_1}; \quad \frac{\delta s_E}{b} = \frac{\delta s_C}{l_2},$$

whence

$$\delta s_E = \frac{bl_1}{al_2} \delta s_B,$$

and consequently

$$N_B = \frac{bl_1}{al_2} P.$$

Fig. 363.

If we used the methods of geometrical statics we would have to consider the equilibrium of each beam separately, introduce the reactions of the other supports, and then eliminate them from the obtained set of equilibrium equations.

Problem 163. The epicyclic gear train in Fig. 364 (see also § 96) consists of a gear 1 of radius r_1 , an arm AB mounted on axle A independently of the gear, and a gear 2 of radius r_2 mounted on the arm at B as shown. Acting on the arm is a torque M , and acting on the gears are resistance moments M_1 and M_2 , respectively. Determine the values of M_1 and M_2 at which the mechanism is in equilibrium.

Solution. The mechanism has two degrees of freedom, since it has two possible independent displacements: the rotation of the arm AB when gear 1 is at rest, and the rotation of gear 1 when the arm is at rest. First consider a virtual displacement of the system in which gear 1 remains at rest (Fig. 364a). For this displacement Eq. (71) gives

$$M \delta\varphi_{AB} - M_2 \delta\varphi_2 = 0.$$

But when gear 1 is at rest the contact point of the gears will be the instantaneous centre of zero velocity of gear 2, and consequently $v_B = \omega_2 r_2$. At the same time, $v_B = \omega_{AB} (r_1 + r_2)$. Hence, $\omega_2 r_2 = \omega_{AB} (r_1 + r_2)$, or $\delta\varphi_2 r_2 = \delta\varphi_{AB} (r_1 + r_2)$, and we obtain

$$M_2 = \frac{r_2}{r_1 + r_2} M.$$

Fig. 364.

Now consider a virtual displacement in which the arm AB remains at rest (Fig. 364*b*). For this displacement Eq. (71) gives

$$M_1 \delta \varphi_1 - M_2 \delta \varphi_2 = 0.$$

But when the arm is at rest

$$\frac{\delta \varphi_2}{\delta \varphi_1} = \frac{\omega_2}{\omega_1} = \frac{r_1}{r_2} \quad \text{and} \quad M_1 = \frac{r_1}{r_2} M_2.$$

We finally obtain

$$M_1 = \frac{r_1}{r_1 + r_2} M, \quad M_2 = \frac{r_2}{r_1 + r_2} M.$$

Problem 164. Determine the relation between forces Q and P at which the press in Fig. 365 is in equilibrium if angles α and β are known. Neglect the weight of the rods.

Solution. To give an example of the analytical method of solution, let us take equilibrium condition (72). Placing the origin of a coordinate system in the fixed point A and drawing the x and y axes as shown, we obtain

Fig. 365.

$$Q_{1x} \delta x_1 + Q_{2x} \delta x_2 + P_{3y} \delta y_3 = 0, \quad (a)$$

since all the other projections of the forces vanish.

To find δx_1 , δx_2 , δy_3 , compute the coordinates x_1 , x_2 , y_3 of the points of application of the forces, expressing them in terms of the angles α and β . Denoting the length of each rod by a , we obtain:

$$x_1 = a \cos \alpha, \quad x_2 = a \cos \alpha + 2a \cos \beta, \\ y_3 = a (\sin \beta + \sin \alpha),$$

differentiating which, we find

$$\delta x_1 = -a \sin \alpha \delta \alpha, \quad \delta x_2 = -a (\sin \alpha \delta \alpha + 2 \sin \beta \delta \beta), \\ \delta y_3 = a (\cos \beta \delta \beta + \cos \alpha \delta \alpha).$$

Substituting these expressions into equation (a) and taking into account that $Q_{1x} = Q$, $Q_{2x} = -Q$, and $P_{3y} = -P$, we have

$$2Q \sin \beta \delta \beta - P (\cos \beta \delta \beta + \cos \alpha \delta \alpha) = 0. \quad (b)$$

To find the relation between $\delta \alpha$ and $\delta \beta$ we make use of the fact that $AB = \text{const.}$ Therefore, $2a (\cos \alpha + \cos \beta) = \text{const.}$ Differentiating this equation, we obtain

$$\sin \alpha \delta \alpha + \sin \beta \delta \beta = 0 \quad \text{and} \quad \delta \alpha = -\frac{\sin \beta}{\sin \alpha} \delta \beta.$$

Substituting the expression for $\delta \alpha$ into equation (b), we have

$$2Q \sin \beta - P (\cos \beta - \cot \alpha \sin \beta) = 0,$$

whence

$$P = \frac{2Q}{\cot \beta - \cot \alpha}.$$

At an angle β very close to α the pressure P will be very large.

167. The General Equation of Dynamics. The principle of virtual work gives a general method for solving problems of statics. On the other hand, D'Alembert's principle makes it possible to employ the methods of statics in solving dynamical problems. It seems obvious that by combining both these principles we can develop a general method for the solution of problems of dynamics.

Consider a system of material particles subjected to ideal constraints. If we add to all the particles subjected to active forces F_k^a and the reaction forces N_k the corresponding inertia forces $F_k^i = -m_k w_k$, then by D'Alembert's principle the resulting force system will be in equilibrium. If we now apply the principle of virtual work, we obtain

$$\sum \delta A_k^a + \sum \delta A_k^i + \sum \delta A_k^N = 0.$$

But from Eq. (70) the last summation is zero, and we finally obtain

$$\sum \delta A_k^a + \sum \delta A_k^i = 0. \quad (73)$$

Equation (73) represents the general equation of dynamics. It states that in a moving system with ideal constraints the total virtual work done by all the active forces and all the inertia forces in any virtual displacement is zero at any instant.

In analytical form Eq. (73) gives

$$\sum [(F_{kx}^a + F_{kx}^i) \delta x_k + (F_{ky}^a + F_{ky}^i) \delta y_k + (F_{kz}^a + F_{kz}^i) \delta z_k] = 0. \quad (74)$$

Equations (73) and (74) make it possible to develop the equations of motion for any mechanical system.

If a system consists of a number of rigid bodies, the relevant equations can be developed if to the active forces applied to each body are added a force equal to the principal vector of the inertia forces applied at any centre, and a couple of moment equal to the principal moment of the inertia forces with respect to that centre. Then the principle of virtual work can be used.

Problem 165. A centrifugal-type governor consists of two balls A_1 and A_2 of weight p each (Fig. 366). The slide C_1C_2 weighs Q , the governor rotates about the vertical axis with a uniform angular velocity ω . Neglecting the weight of the rods, determine angle α , if $OA_1 = OA_2 = l$, and $OB_1 = OB_2 = B_1C_1 = B_2C_2 = a$.

Solution. Adding to the active forces p_1, p_2 , and Q , the centrifugal inertia forces F_1^i and F_2^i (the inertia force of the slide will, evidently, be zero), we write the general equation of dynamics in the form (74). Computing the projections of all the forces on the coordinate axes, we have

$$p_1 \delta x_1 + p_2 \delta x_2 - F_1^i \delta y_1 + F_2^i \delta y_2 + Q \delta x_3 = 0. \quad (a)$$

We also have:

$$Q_3 = Q; \quad \rho_1 = \rho_2 = \rho; \quad F_1^i = F_2^i = \frac{\rho}{g} \omega_A = \frac{\rho}{g} \omega^2 l \sin \alpha.$$

The coordinates of the points of application of the forces are

$$x_1 = x_2 = l \cos \alpha, \quad y_2 = -y_1 = l \sin \alpha, \quad x_3 = 2a \cos \alpha.$$

Differentiating these expressions, we find

Fig. 366.

Fig. 367.

Substituting all these expressions into equation (a), we obtain

$$\left(-2\rho l \sin \alpha + 2 \frac{\rho}{g} l^2 \omega^2 \sin \alpha \cos \alpha - 2Qa \sin \alpha \right) \delta \alpha = 0,$$

whence we finally have

$$\cos \alpha = \frac{\rho l + Qa}{\rho l^2 \omega^2} g.$$

As $\cos \alpha \leq 1$, the balls will move apart when

$$\omega^2 > \frac{\rho l + Qa}{\rho l^2} g.$$

Angle α increases with ω and tends to 90° when $\omega \rightarrow \infty$.

Problem 166. In the hoist mechanism in Fig. 367, a torque M is applied to gear 2 of weight P_2 and radius of gyration ρ_2 . Determine the acceleration of the lifted load A of weight Q , neglecting the weight of the string and the friction in the axles. The drum on which the string winds and the gear 1 attached to it have a total weight P_1 and a radius of gyration ρ_1 . The radii of the gears are r_1 and r_2 , and of the drum r .

Solution. Draw the active force Q and torque M (forces P_1 and P_2 do no work) and add to them the inertia force F_A^i of the load and the couples of moments M_1^i and M_2^i to which the inertia forces of the rotating bodies are

reduced (see § 159). In magnitude these quantities are:

$$F_A^i = \frac{Q}{g} \omega_A, \quad |M_1^i| = \frac{P_1}{g} \varrho_1^2 \varepsilon_1, \quad |M_2^i| = \frac{P_2}{g} \varrho_2^2 \varepsilon_2.$$

The directions of all the vectors are shown in the diagram. Writing Eq. (73) for a virtual displacement of the system, we obtain

$$-(Q + F_A^i) \delta s_A - M_1^i \delta \varphi_1 + (M - M_2^i) \delta \varphi_2 = 0.$$

Expressing all the displacements in terms of $\delta \varphi_1$, we have

$$\delta s_A = r \delta \varphi_1, \quad \frac{\delta \varphi_2}{\delta \varphi_1} = \frac{\omega_2}{\omega_1} = \frac{r_1}{r_2} \quad \text{and} \quad \delta \varphi_2 = \frac{r_1}{r_2} \delta \varphi_1.$$

Finally the equation of motion takes the form

$$Q \left(1 + \frac{\omega_A}{g} \right) r + \frac{P_1}{g} \varrho_1^2 \varepsilon_1 + \frac{P_2}{g} \varrho_2^2 \varepsilon_2 \frac{r_1}{r_2} - M \frac{r_1}{r_2} = 0.$$

Now express the quantities ε_1 and ε_2 in terms of the required acceleration ω_A . Taking into account that ε_1 and ε_2 are related in the same way as ω_1 and ω_2 , we obtain

$$\varepsilon_1 = \frac{\omega_A}{r}, \quad \varepsilon_2 = \frac{r_1}{r_2} \varepsilon_1 = \frac{r_1}{r_2} \frac{\omega_A}{r}.$$

and finally we have

$$\omega_A = \frac{\frac{r_1}{r_2} M - rQ}{rQ + \frac{\varrho_1^2}{r} P_1 + \frac{\varrho_2^2}{r} \frac{r_1^2}{r_2^2} P_2} g.$$

An alternate solution of this problem is with the help of the theorem of the change in kinetic energy (see § 150).

Problem 167. One end of a thread is wound on a uniform cylinder of weight p_1 (Fig. 368). The thread passes over a pulley O , and its other end is attached to a load A of weight p_2 which slides on a horizontal plane, the coefficient of friction being f . Neglecting the mass of the pulley and the string, determine the acceleration of the load and of the centre C of the cylinder.

Solution. If motion starts from rest, the centre of the cylinder C will move vertically, and the system has two degrees of freedom (the rotation of the cylinder with respect to the thread when the load is at rest and the displacement of the load when the cylinder does not rotate).

Add to the acting forces p_1 , p_2 , and F_{fr} the inertia forces of the cylinder reduced to a principal vector R_C^i and a couple of moment M_C^i (see § 159), and the inertia force F_A^i of the load. In magnitude

$$F_A^i = \frac{p_2}{g} \omega_A, \quad R_C^i = \frac{p_1}{g} \omega_C, \quad |M_C^i| = J_C \varepsilon = \frac{p_1}{2g} r^2 \frac{\omega_C - \omega_A}{r}.$$

Fig. 368.

The last equality follows from the fact that, if point C of the cylinder has a velocity v_C , and point B (together with the string) a velocity $v_B = v_A$, then the angular velocity of the cylinder $\omega = \frac{v_C - v_A}{r}$ [see § 81, Eq. (56)], and, consequently, $\varepsilon = \frac{\omega_C - \omega_A}{r}$; furthermore, for the cylinder $J_C = 0,5mr^2$, where r is the radius of the cylinder.

Now consider a virtual displacement δs_A of the system in which the cylinder does not rotate and is translated together with the load. The couple of moment M_C^i does no work in this displacement, and from Eq. (73) we obtain

$$(-F_{fr} - F_A^i - R_1^i + p_1)\delta s_A = 0,$$

whence, as $F_{fr} = fp_2$, we find

$$\frac{p_1}{g}\omega_C + \frac{p_2}{g}\omega_A = p_1 - fp_2. \quad (a)$$

Consider the other independent virtual displacement in which the load A remains at rest while the cylinder turns about point B (which in this displacement is the instantaneous centre of rotation) through angle $\delta\varphi$. For this displacement, Eq. (73) gives

$$(p_1 - R_1^i)r\delta\varphi - M_C^i\delta\varphi = 0.$$

Substituting the expressions for R_1^i and M_C^i , we obtain

$$3\omega_C - \omega_A = 2g. \quad (b)$$

Solving equations (a) and (b) simultaneously, we obtain the required accelerations:

$$\omega_A = \frac{p_1 - 3fp_2}{p_1 + 3p_2}g, \quad \omega_C = \frac{p_1 + (2-f)p_2}{p_1 + 3p_2}g.$$

The result shows that the motion considered is possible when $f \leq p_1/3p_2$. If the coefficient of friction is greater, load A will remain at rest, the displacement δs_A will not be possible and there will be no equation (a). The motion of the centre of the cylinder will be described by equation (b), if in the latter ω_A is taken to be zero. Consequently, at $f > p_1/3p_2$, load A will be at rest while the centre C of the cylinder will fall with an acceleration $\omega_C = 2/3g$.

Note that for systems with more than one degree of freedom the method for developing equations described in § 150 is useless and the general equation of dynamics must be applied.

Chapter 31

THE THEORY OF IMPACT

168. The Fundamental Equation of the Theory of Impact. In motion under the action of conventional forces treated hitherto, the velocities of the points of a body change continuously, i.e., to any infinitesimal time interval there corresponds an infinitesimal velocity increment. For, if we represent the linear impulse

of any force F_k in a time interval τ in the form $F_k^{av}\tau$, where F_k^{av} is the average value of this force in the time interval τ , the theorem of the change in the momentum of a particle acted upon by forces F_k gives

$$m(v_1 - v_0) = \sum F_k^{av}\tau. \quad (75)$$

We see from this that when the time τ is infinitesimal (tends to zero), for conventional forces the velocity increment $\Delta v = v_1 - v_0$ will also be infinitesimal (will tend to zero).

If, however, the acting forces include very large forces (of the order $1/\tau$), the velocity increment in the small time interval τ will become a finite quantity.

The phenomenon in which the velocities of the points of a body suffer a finite change in a very small time interval τ is called *impact*. We shall call the forces developed during impact *impulsive forces*, or *forces of impact* (denoted F_{imp}) and the very small time interval τ during which collision takes place, the *impact time*.

As impulsive forces are very large and change within considerable limits in the impact time, the theory of impact considers not the impulsive forces themselves as a measure of the interaction of colliding bodies, but their impulses. The impulse of a force of impact

$$S_{imp} = \int_0^\tau F_{imp} dt = F_{imp}^{av}\tau$$

is a finite quantity. The impulses of non-impulsive forces in the time interval τ will be very small and for all practical purposes can be neglected.

Denoting the velocity of a particle at the beginning of impact—the velocity of approach—by the symbol v , and the velocity at the end of impact—the velocity of separation—by u , Eq. (75) takes the form

$$m(u - v) = \sum S_k. \quad (76)$$

This equation states the theorem of the change in the momentum of a particle during impact: *The change in the linear momentum of a particle during impact is equal to the sum of the impulses of the forces of impact acting on the particle.* Eq. (76) is the fundamental equation of the theory of impact and it plays the same role in the theory of impact as the fundamental law of dynamics $m\dot{v} = F$ does in studying motion under the action of non-impulsive forces.

Finally, the displacement of a particle during impact is equal to $v^{av}\tau$, a very small quantity which in practice can be neglected.

From the above discussion we conclude:

- 1) The action of non-impulsive forces (the force of gravity, for example) in the time of impact can be neglected;
- 2) The displacement of the points of a body in the time of impact can be neglected and the body regarded as motionless;
- 3) The change in the velocities of the points of a body during impact is defined by the fundamental equation of the theory of impact (76).

169. General Theorems of the Theory of Impact. The following theorems are used in investigating impact in a system of particles or bodies.

1. The Theorem of the Change in the Linear Momentum of a System in Impact. Consider a system of n particles, denoting the resultant impulse of all the external forces of impact acting on a particle of mass m_k by the symbol S_k^e , and the resultant impulse of all the internal forces of impact by the symbol S_k^i . Then, from Eq. (76), we have

$$m_k(u_k - v_k) = S_k^e + S_k^i. \quad (77)$$

Writing similar equations for all the particles of the system and adding them, we obtain

$$\sum m_k u_k - \sum m_k v_k = \sum S_k^e + \sum S_k^i.$$

The summations in the left side represent the moments of the system at the end and the beginning of the impact, which we shall denote by the symbols Q_1 and Q_0 . The total impulse of the internal forces of impact in the right side of the equation is, by the property of internal forces, zero. We thus obtain:

$$Q_1 - Q_0 = \sum S_k^e, \quad (78)$$

i.e., the change in the momentum of a system during impact is equal to the total impulse of all the external forces of impact acting on the system.

For the projections on any coordinate axis x , Eq. (78) gives:

$$Q_{1x} - Q_{0x} = \sum S_{kx}^e. \quad (79)$$

If the geometrical sum of the total impulse of the external forces of impact is zero, then, as can be seen from Eq. (78), the linear momentum of the system will not change during impact. Consequently, the internal impulses cannot change the linear momentum of the system as a whole.

2. The Theorem of the Change in the Total Angular Momentum of a System (the Principle of

Moments) During Impact. Reasoning as in the foregoing case, let us write Eq. (77) for a particle of mass m_k in the form

$$m_k u_k = m_k v_k + S_k^e + S_k^i.$$

The vectors in this equation are applied to a particle which remains motionless during the impact. Hence, taking the moments of all the vectors with respect to any centre O , we obtain by Varignon's theorem, which is valid for any vector quantities,

$$m_o(m_k u_k) = m_o(m_k v_k) + m_o(S_k^e) + m_o(S_k^i).$$

Writing such equations for all the particles of a system and adding them, we obtain

$$\sum m_o(m_k u_k) - \sum m_o(m_k v_k) = \sum m_o(S_k^e) + \sum m_o(S_k^i).$$

The summations in the left side represent the total angular momentum of system with respect to O at the end and the beginning of the impact, which we shall denote K_1 and K_0 , respectively. From the property of internal forces, the sum of the moments of the internal impulses in the right side of the equation is zero. Thus, we finally have

$$K_1 - K_0 = \sum m_o(S_k^e), \quad (80)$$

i.e., the change during impact of the total angular momentum of a system with respect to any centre is equal to the sum of the momenta of all the external impulses acting on the system taken with respect to the same centre.

For the projections on any axis x , Eq. (80) gives

$$K_{1x} - K_{0x} = \sum m_x(S_k^e). \quad (81)$$

It follows from these equations that if the sum of the moments of all external impulses with respect to any centre (or axis) is zero, then the total angular momentum of the system with respect to the centre (or axis) will not change during the impact. Consequently, internal impulses cannot change the total angular momentum of a system.

The theorem of the change in kinetic energy is not used to solve the fundamental problem of dynamics in the theory of impact as all the particles of a body are considered motionless during impact, and instead of the forces of impact their impulses are considered. Therefore, it is not possible to calculate directly (from the force and displacement) the work done by impulsive forces. Later on we shall consider only the question of determining the loss in the kinetic energy of bodies during impact (§ 173).

170. Coefficient of Restitution. The magnitude of the impulse when two bodies collide depends not only on their masses and

velocities before impact, but also on their elastic or plastic properties, which are characterised by the *coefficient of restitution*.

Consider a sphere falling vertically on a fixed horizontal plate (Fig. 369). There are two stages in the direct impact that will take place between them. During the first stage, known as the period of deformation, the velocities of the particles of the sphere, which at the beginning of the impact are v (assuming the sphere to be in translatory motion) drop to zero. The sphere deforms

(assuming the plate to be rigid) and its total initial kinetic energy $\frac{1}{2} Mv^2$ turns into the internal potential energy of deformation. During the second stage of the impact, known as the period of restitution, the internal elastic forces of the sphere work to restore its shape and the internal potential energy turns into the kinetic energy of motion of the particles of the sphere. At the end of the impact, the velocities of the particles will be u , and the kinetic energy of the sphere, $\frac{1}{2} Mu^2$. Actually, however, the mechanical energy of

the sphere is not restored completely, as part of it is spent on giving the sphere some residual deformation and on heating it. Therefore, u is always less than v .

The coefficient of restitution k for direct impact of a body against a fixed obstacle is equal to the ratio of the magnitudes of the velocity of separation to the velocity of approach:

$$k = \frac{u}{v}. \quad (82)$$

The coefficient of restitution for different bodies is determined experimentally. Experiments show that for changes of the velocity v within small limits the value of k depends only on the material of the colliding bodies.

The limiting values of k are $k=1$ for *perfectly elastic impact* in which the mechanical energy of a body is completely restored after impact, and $k=0$ for *perfectly inelastic impact* when the impact ends with the end of the period of deformation and the mechanical energy of a body is lost completely in deformation and heating.

The coefficient of restitution is determined experimentally by investigating the free fall of a sphere from a known height H to a plate. The height of the rebound h is then measured on a vertical rule (Fig. 370). From Galileo's formula,

$$v = \sqrt{2gH} \quad \text{and} \quad u = \sqrt{2gh},$$

whence

$$k = \frac{u}{v} = \sqrt{\frac{h}{H}}.$$

Coefficients of restitution for some bodies with a velocity of approach in the order of 3 m/sec are given in the table below.

Colliding bodies	k
Wood on wood	1/2
Steel on steel	5/9
Ivory on ivory	8/9
Glass on glass	15/16

Fig. 370.

171. Impact of a Body Against a Fixed Obstacle. Consider a body (sphere) of mass M hitting a fixed plate. The impulsive force acting on the body will be the reaction of the plate. Let us denote by S the impulse of this force during the impact. If the normal to the surface of the body at its point of contact with the plate passes through the centre of mass of the body (for a sphere this is always the case) the impact is called *central* impact. If the velocity of approach v of the centre of mass of the body is directed along the normal n to the plate, the impact is called *direct* impact; otherwise it is *oblique* impact.

1. **Direct Impact.** Writing Eq. (79) in terms of the projections on the normal n (see Fig. 369), and taking into account that $Q_0 = Mv$ and $Q_1 = Mu$, we obtain

$$M(u_n - v_n) = S_n.$$

But in direct impact $u_n = u$, $v_n = -v$, and $S_n = S$. Consequently,

$$M(u + v) = S.$$

The second equation necessary to solve problems is given by Eq. (82): $u = kv$.

Knowing M , v , and k , we can obtain from these equations the unknown quantities u and S . We have

$$S = M(k + 1)v.$$

We see that the greater the coefficient of restitution k , the greater the impulse in impact. This dependence between S and k was pointed out in § 170.

In order to determine the average value of the impulsive force (the reaction) we must also know the time of impact τ , which can be found experimentally.

Example. When a steel sphere of weight $p = 1$ kg falls from a height $H = 3$ m on a steel plate ($k = 5/9$), we have $v = \sqrt{2gH} \approx 7.7$ m/sec, and $u = kv \approx 4.3$ m/sec. The impulse of impact will be

$$S = \frac{p}{g} v (1 + k) \approx 1.2 \text{ kg}\cdot\text{sec}.$$

If the time of impact $\tau = 0.0005$ sec, the average value of the impulse reaction will be

$$N_{\text{imp}}^{\text{av}} = \frac{S}{\tau} = 2,400 \text{ kg}.$$

2. Oblique Impact. Let the velocity of approach v of the centre of mass of a body make an angle α with the normal to a plate, and the velocity of separation u an angle β (Fig. 371). Then Eq. (78) in terms of the projections on the tangent τ and the normal n gives

Fig. 371.

$$M(u_{\tau} - v_{\tau}) = 0, \quad M(u_n - v_n) = S.$$

The coefficient of restitution in this case is equal to the ratio of the magnitudes of $|u_n|$ and $|v_n|$, as impact acts only along the normal to the surface (we neglect friction). Then, taking the signs into account, we obtain $u_n = -kv_n$, and finally we have

$$u_{\tau} = v_{\tau}, \quad u_n = -kv_n, \quad S = M|v_n|(1 + k).$$

These equations enable us to find the magnitude and direction of the velocity of separation and the impulse of the forces of impact if the quantities M , v , α , and k are known. In particular, noting that $v_{\tau} = |v_n| \tan \alpha$ and $u_{\tau} = |u_n| \tan \beta$, from the first equation we obtain $|u_n| \tan \beta = |v_n| \tan \alpha$, whence

$$k = \frac{|u_n|}{|v_n|} = \frac{\tan \alpha}{\tan \beta}.$$

Thus, in oblique impact the coefficient of restitution equals the ratio of the tangent of the angle of approach to the tangent of the angle of rebound. As $k < 1$, $\alpha < \beta$, i.e., the angle of rebound is always smaller than the angle of approach.

172. Direct Central Impact of Two Bodies (Impact of Spheres). Impact of two colliding bodies is said to be *direct* and *central* when the common normal to the surfaces of the bodies through their point of contact passes through their centres of mass and when the approach velocities of the centres of mass are directed along this common normal. An example of direct central impact is the collision of two homogeneous balls whose centres moved collinearly before impact.

Let us denote the masses of the colliding bodies by M_1 and M_2 , their approach velocities by v_1 and v_2 , and their velocities of separation by u_1 and u_2 . Draw through their centres of mass C_1 and C_2 a coordinate axis C_1x , always directed from C_1 to C_2 (Fig. 372). For a collision to take place, we must have $v_{1x} > v_{2x}$ (otherwise the first body will never catch up with the second); furthermore we shall have $u_{1x} \leq u_{2x}$, since a body hitting another body can never overtake it.

Assuming that M_1 , M_2 , v_{1x} , v_{2x} , and k are known, let us find u_1 and u_2 . For this let us apply the theorem of the change in linear momentum to the colliding bodies. If we consider them as a single system, the forces of impact will be internal, and $\sum S_{\text{imp}}^e = 0$. As a result, Eq. (79) gives $Q_{1x} = Q_{0x}$, or

$$M_1 u_{1x} + M_2 u_{2x} = M_1 v_{1x} + M_2 v_{2x}. \quad (83)$$

The second equation is obtained from the expression for the coefficient of restitution. When two bodies collide the impulses of the forces of impact depend only on the relative velocity of the bodies, i.e., on the difference $v_{1x} - v_{2x}$. Therefore, for two colliding bodies, taking into account that always $v_{1x} > v_{2x}$ and $u_{1x} \leq u_{2x}$, we obtain

$$k = \left| \frac{u_{1x} - u_{2x}}{v_{1x} - v_{2x}} \right| = - \frac{u_{1x} - u_{2x}}{v_{1x} - v_{2x}}, \quad (84)$$

or

$$u_{1x} - u_{2x} = -k(v_{1x} - v_{2x}). \quad (84')$$

The set of equations (83), (84) makes it possible to solve the problem. The impulse of the forces of impact can be found by

Fig. 372.

writing Eq. (79) for one of the bodies, the first, for instance. Then

$$S_{1x} = M_1(u_{1x} - v_{1x}), \quad S_{2x} = -S_{1x}. \quad (85)$$

Let us consider two limiting cases.

a) **Perfectly Inelastic Impact** ($k=0$). In this case, from Eqs. (84) and (83) we find

$$u_{1x} = u_{2x} = \frac{M_1 v_{1x} + M_2 v_{2x}}{M_1 + M_2}. \quad (86)$$

After impact both bodies move with the same velocity. The impulse of the forces of impact acting on the bodies is

$$S_{2x} = -S_{1x} = \frac{M_1 M_2}{M_1 + M_2} (v_{1x} - v_{2x}).$$

b) **Perfectly Elastic Impact** ($k=1$). In this case, from Eqs. (83) and (84) we obtain

$$\left. \begin{aligned} u_{1x} &= v_{1x} - \frac{2M_2}{M_1 + M_2} (v_{1x} - v_{2x}), \\ u_{2x} &= v_{2x} + \frac{2M_1}{M_1 + M_2} (v_{1x} - v_{2x}). \end{aligned} \right\} \quad (87)$$

The impulse of the forces of impact is

$$S_{2x} = -S_{1x} = \frac{2M_1 M_2}{M_1 + M_2} (v_{1x} - v_{2x}).$$

We see that for perfectly elastic impact the impulse is double the impulse in perfectly inelastic impact.

In the special case when $M_1 = M_2$ we obtain from Eqs. (87)

$u_{1x} = v_{2x}$, $u_{2x} = v_{1x}$. Thus, in perfectly elastic impact two bodies of equal mass exchange their velocities.

Fig. 373.

Problem 168. Two balls of masses M_1 and M_2 are suspended as shown in Fig. 373. The first ball is pulled back through an angle α and let go from rest. After impact, the second ball swings away through an angle β . Find the coefficient of restitution for the balls.

Solution. The conditions of the problem make it possible to find the velocity of approach v_1 of the centre of the first ball and the velocity of separation u_2 of the centre of the second ball. From the theorem of the change in kinetic energy in a displacement $B_0 B_1$, we find for the first ball

$$\frac{1}{2} M_1 v_1^2 = P_1 h = M_1 g l (1 - \cos \alpha),$$

where l is the distance of the centre of the ball from the point of suspension. Hence,

$$v_1 = 2 \sqrt{gl} \sin \frac{\alpha}{2}.$$

Similarly, we find that

$$u_2 = 2 \sqrt{gl} \sin \frac{\beta}{2}.$$

Since in our case $v_2 = 0$, Eqs. (83) and (84) give

$$M_1 u_{1x} + M_2 u_{2x} = M_1 v_{1x}, \quad u_{2x} - u_{1x} = k v_{1x}.$$

Eliminating u_{1x} and noting that $v_{1x} = v_1$ and $u_{2x} = u_2$, we obtain

$$M_1 v_1 (1 + k) = (M_1 + M_2) u_2,$$

and finally we have

$$k = \frac{(M_1 + M_2) u_2}{M_1 v_1} - 1 = \frac{(M_1 + M_2) \sin \frac{\beta}{2}}{M_1 \sin \frac{\alpha}{2}} - 1.$$

173. Loss of Kinetic Energy in Perfectly Inelastic Impact. Carnot's Theorem. It follows from the reasoning in § 170 that in inelastic impact the colliding bodies lose kinetic energy. This loss is greatest in the case of perfectly inelastic impact. Let us calculate the amount of kinetic energy lost by a system of two bodies in perfectly inelastic impact.

Considering the colliding bodies to be in translatory motion and denoting their common velocity after impact by u , we obtain for the kinetic energy of the system at the beginning and the end of impact

$$T_0 = \frac{1}{2} (M_1 v_{1x}^2 + M_2 v_{2x}^2), \quad T_1 = \frac{1}{2} (M_1 + M_2) u_x^2. \quad (88)$$

The kinetic energy lost in impact will be $T_0 - T_1$. Let us write this difference in the form

$$T_0 - T_1 = T_0 - 2T_1 + T_1. \quad (89)$$

As, from Eq. (86),

$$(M_1 + M_2) u_x = M_1 v_{1x} + M_2 v_{2x},$$

then

$$2T_1 = (M_1 + M_2) u_x^2 = (M_1 v_{1x} + M_2 v_{2x}) u_x. \quad (90)$$

Substituting into the right side of Eq. (89) the expressions for T_0 and T_1 from formulas (88), and for $2T_1$ the right side of Eq. (90), we obtain

$$T_0 - T_1 = \frac{1}{2} (M_1 v_{1x}^2 + M_2 v_{2x}^2 - 2M_1 v_{1x} u_x - 2M_2 v_{2x} u_x + M_1 u_x^2 + M_2 u_x^2),$$

or

$$T_0 - T_1 = \frac{1}{2} M_1 (v_{1x} - u_x)^2 + \frac{1}{2} M_2 (v_{2x} - u_x)^2. \quad (91)$$

The differences $(v_{1x} - u_x)$ and $(v_{2x} - u_x)$ give the velocity lost by each body as a result of the impact. From Eq. (91) follows Carnot's* theorem: *The kinetic energy lost by a system of bodies in a perfectly inelastic impact is equal to the kinetic energy the system would have had if its bodies moved with the lost velocities.*

Let us consider the special case of collision with a body initially at rest. In this case $v_2 = 0$ and

$$T_0 = \frac{1}{2} M_1 v_1^2, \quad u = \frac{M_1 v_1}{M_1 + M_2},$$

then

$$T_1 = \frac{1}{2} (M_1 + M_2) u^2 = \frac{1}{2} \frac{M_1^2 v_1^2}{M_1 + M_2} = \frac{M_1}{M_1 + M_2} \frac{M_1 v_1^2}{2},$$

or

$$T_1 = \frac{M_1}{M_1 + M_2} T_0. \quad (92)$$

Eq. (92) gives the energy left in a system after impact. Let us consider two interesting extremes.

a) Mass of Hitting Body Is Much Greater than Mass of Hit Body ($M_1 \gg M_2$). In this case we may consider

$$M_1 + M_2 \approx M_1,$$

and Eq. (92) gives $T_1 \approx T_0$. Thus, even if impact is perfectly inelastic, there is practically no loss of kinetic energy and the system moves after impact with practically the same kinetic energy it had at the beginning of the impact.

In practice this is of importance, for example, in hammering nails, driving piles, etc. Clearly, the mass of the hammer should be much greater than the mass of the nail (Fig. 374a).

b) Mass of Hit Body Is Much Greater than Mass of Hitting Body ($M_2 \gg M_1$). In this case we may consider

$$\frac{M_1}{M_1 + M_2} \approx 0,$$

* Lazare Carnot (1753-1823), an outstanding French mathematician and mechanic and a prominent public figure in the French Revolution.

and Eq. (92) gives $T_1 \approx 0$, i.e., practically all the kinetic energy is lost on deformation and at the end of impact the bodies may be considered motionless.

In practice this is of importance in forging, riveting, etc. In these cases, therefore, the combined mass of forging and anvil (or rivet and support) should be much greater than the mass of the hammer (Fig. 374b)

Fig. 374.

174. Impact with a Rotating Body. Consider a body rotating about an axis z (Fig. 375). Let an impact impulse S be applied at any instant to the body. Then, from Eq. (81), we have

$$K_{1z} - K_{0z} = m_z(S),$$

as the moments with respect to the z axis of the impulse reactions S_A and S_B in the bearings are zero. If at the beginning of impact the body had an angular velocity ω_0 , and at the end of impact its angular velocity became ω_1 , then $K_{0z} = J_z \omega_0$ and $K_{1z} = J_z \omega_1$, and we obtain

$$J_z (\omega_1 - \omega_0) = m_z(S) \quad (93)$$

or

$$\omega_1 = \omega_0 + \frac{m_z(S)}{J_z}. \quad (93')$$

Eq. (93) gives the change in the angular velocity of a body due to impact. It follows from the equation that *the change in the angular velocity of a body during impact is equal to the ratio of the moment of the impulse of impact to the moment of inertia of the body, both moments taken with respect to the axis of rotation.*

Centre of Impact. Impact gives rise to impulsive reactions at the points of support of an axis, which may lead to

Fig. 375.

greater wear and tear of machine parts (especially bearings, shafts, etc.), and even to their complete breakdown. Let us determine the conditions in which impact with a body mounted on a shaft will not cause impulsive pressures in its bearings.

First of all, the masses of the body should be dynamically balanced with respect to the plane in which impact takes place, for example this plane can coincide with the plane of symmetry of the body*. Consider a body having a plane of symmetry Oxy and mounted on an axis AB perpendicular to that plane and free to rotate in bearings A and B (Fig. 376). Draw an axis Oy through the centre of mass C of the body and denote the distance $OC = a$.

Let us assume that the body was at rest at the beginning of impact ($\omega_0 = 0$). This assumption does not alter the final result.

The impulse S of the forces of impact in the plane of symmetry develops impulsive reactions S_A and S_B in the bearings. Then, from Eq. (78), we have

$$Q_1 - Q_0 = S + S_A + S_B. \quad (94)$$

In our case $Q_0 = 0$ and $Q_1 = Mu_C$, where u_C is the velocity of the centre of mass C of the body at the end of impact. From Eq. (94) we see that the conditions $S_A = S_B = 0$ can be satisfied when $S = Mu_C$.

It follows from this that the impulse S should be parallel to

the velocity u_C , i.e., perpendicular to OC (to the y axis). Furthermore, as the vectors are equal, their magnitudes must be equal. Hence

$$S = Mu_C = Ma\omega_1.$$

But, by Eq. (93'),

$$\omega_1 = \frac{m_z(S)}{J_z} = \frac{Sh}{J_z}.$$

* For the sake of simplicity, the case is considered when a body has a plane of symmetry Oxy perpendicular to its axis z . The results, however, are all valid for any case when there is no symmetry, but impact is in the plane Oxy through a point O with respect to which axis z is the principal axis of inertia of the body.

Fig. 376.

Substituting this quantity into the previous equation, we obtain

$$h = \frac{J_z}{Ma}. \quad (95)$$

Eq. (95) defines the distance h from the axis at which the impulse of impact must be applied.

Thus, in order to prevent the generation of impulsive reactions in the points of support of an axis z fixed in a body the following conditions are necessary:

1) that the impact be in the plane Oxy perpendicular to the axis z , Oxy being the plane of symmetry of the body (or the axis of rotation z should be the principal axis of inertia with respect to its point of intersection with that plane, i.e., with respect to point O);

2) that the impact be directed perpendicular to the plane through the axis of rotation Az and the centre of mass C of the body;

3) that the impulse of impact be applied at a distance $h = \frac{J_z}{Ma}$ from the axis (on the same side of the axis as the centre of mass).

The point K through which will pass the impulse without causing impulsive reactions in the points of support of the axis is called the *centre of impact*.

Note that, from Eq. (95), the centre of impact coincides with the centre of percussion of a compound pendulum. Therefore, as was shown in § 154, $h > a$, i.e., the distance from the axis to the centre of impact is greater than to the centre of mass. If the axis of rotation passes through the centre of mass, then $a = 0$ and $h = \infty$. In this case the centre of impact is in infinity, and any impact will be transmitted to the axis.

When impact in the plane of symmetry Oxy does not pass through the centre of impact, impulsive reactions S_A and S_B appear in the bearings. When the bearings are located symmetrically, $S_A = S_B$, and these quantities can be obtained from Eq. (94).

Applications of the above results are illustrated by the following examples.

1. In designing a pivoted gunlock hammer (Problem 169) or a pendulum impact-testing machine the axis of rotation should be so chosen that the point of impact should coincide with the centre of impact with respect to the axis.

Fig. 377.

2. In working with a hammer, you should hold the handle so that the hitting end would be the centre of impact with respect to your hand. Failure to do this results in a characteristic "sting".

3. In order not to "sting" your hand when you hit something with a stick (Fig. 377) the blow should be dealt with the point which is the centre of impact with respect to your hand. If we consider the stick to be a homogeneous rod of length l and the axis of rotation to be at the end in your hand, then $a = \frac{l}{2}$, $J_z = \frac{1}{3} Ml^2$, and $h = \frac{J_z}{Ma} = \frac{2}{3} l$.

Thus, in the case shown in Fig. 377, the blow should be dealt with a point of the stick two-thirds of the total distance away from the hand, or one-third of the distance from the opposite end.

Problem 169. At the beginning of impact with the firing pin B of a gunlock, a pivoted hammer AD (Fig. 378) has an angular velocity ω_0 . Determine the acceleration of the firing pin at the end of impact and the impulsive pressure on axis A , if the masses M and m of the hammer and firing pin, the moment of inertia J_A of the hammer with respect to axis A , and the distances a and b are all known. Point C is the centre of mass of the hammer.

Fig. 378.

Solution. Let us denote the impulses acting on the hammer and the firing pin during impact by S_1 and S_2 . Then, taking into account that $S_1 = S_2 = S$ and $v_B = 0$, we obtain for the hammer [by Eq. (93)] and for the firing pin [by Eq. (79)]:

$$J_A(\omega_1 - \omega_0) = -Sb, \quad mu_B = S. \quad (a)$$

The moment Sb is taken with a minus sign because it is directed opposite to the rotation of the hammer. Moreover, since for point D of the hammer $v_D = \omega_0 b$ and $u_D = \omega_1 b$ (v_D is the velocity of approach, and u_D the velocity of separation), equation (84), which gives the coefficient of restitution for direct impact, gives

$$u_D - u_B = -k(v_D - v_B),$$

$$\text{or} \quad \omega_1 b - u_B = -k\omega_0 b.$$

Substituting into this equation the expressions of ω_1 and S from equations (a), we obtain the velocity of the firing pin at the end of impact:

$$u_B = \frac{J_A b (1 + k)}{J_A + mb^2} \omega_0.$$

To determine the impulsive reaction S_A of the axis on the hammer, we write Eq. (94) in terms of the projections on the axes Ax and Ay . Taking into account that

$$Q_{0x} = Mv_{Cx} = M\omega_0 a, \quad Q_{1x} = Mu_{Cx} = M\omega_1 a,$$

we obtain

$$Ma(\omega_1 - \omega_0) = -S + S_{Ax}, \quad S_{Ay} = 0. \quad (b)$$

But from equation (a)

$$S = mu_B, \quad \omega_1 - \omega_0 = -\frac{mb}{J_A} u_B.$$

Substituting these values into equation (b) and replacing u_B by its expression, we obtain finally

$$S_{Ax} = \frac{J_A - Mab}{J_A + mb^2} mb (1 + k) \omega_0.$$

We see from this that at $b = \frac{J_A}{Ma}$, i.e., when point D is the centre of impact, $S_A = 0$. When $Mab < J_A$, we have $S_{Ax} > 0$, i.e., the impulsive pressure on the hammer is directed to the left and the pressure on the axis to the right. At $Mab > J_A$, the pressure on the axis is directed to the left.

 Physical system of units 230
 Pitch 145
 Pivot friction 95
 Plane motion 170, 197, 209, 362
 Plane truss 82
 Planetary transmission 219
 Polar coordinates, velocity in 156
 Polygon,
 cremona 85
 force 25, 78
 funicular 78, 79
 string 78, 79
 vector 25
 Position of impending slip 91
 Potential energy 353
 Power 254, 347
 Precession 370
 Principal
 axes of inertia 382
 central axis of inertia 383
 moment 57, 105
 normal 148
 problem of dynamics 230
 problem of kinematics 129
 vector 57, 105
 vector of inertia forces 374
 Principle
 of moments 264-266, 333
 of relativity 276
 of solidification 19
 of transmissibility 17
 of virtual work 388
 Principles of statics 16
 Product of inertia 382
 Projectile motion 245
 Projection
 of the derivative of a vector 141
 of a force 28
 Propeller 336
 Propulsion,
 jet 326
 propeller 326
 reaction 326
 Quantum mechanics 11
 Radius
 of curvature 149
 of gyration 310
 vector 97, 138
 Reaction 20
 effect 330
 force 330
 moment 336
 of constraints 81, 270
 of supports 81
 propulsion 326
 thrust 330
 torque 336
 Recoil 326
 Rectangular components 30
 Rectilinear motion 129-132, 151, 233
 Reduction of a force system 56, 58, 104, 106
 Reference system, 128
 fixed 198, 228
